ABSTRACT

The Higher-Harmonic Control (HHC) algorithm is re-examined from a rigorous control theory-oriented perspective. A brief review of the history and developments of HHC is given, followed by a careful development of the algorithm. The paper proceeds to perform an analytic convergence and robustness analysis. On-line identification with the adaptive variant of the algorithm is also addressed. A new version of the algorithm, relaxed HHC, is also introduced and shown to have beneficial robustness properties. Some numerical results comparing these variants of the HHC algorithm applied to helicopter vibration reduction are also presented. The results presented in this paper unify and extend previous work on the higher-harmonic control algorithm.

Nomenclature

$0_n$ Zero matrix of size $n \times n$
$A$ Matrix relating plant input and output between updates
$A^*$ Adjoint matrix of $A$, $(A^T)^T$
$D$ Matrix defined to be $T^TQT + R$
$F_f$ Exponential window
$I_n$ Identity matrix of size $n \times n$
$J$ Quadratic-form cost function
$J_{T,\infty}$ Converged cost function for adaptive control
$J_{T,a,\infty}$ Converged cost function for relaxed control
$K_{k+1}$ Matrix defined to be $\Delta u_{k+1}^T P_{k+1}$
$k$ Integer index between control inputs
$m$ Number of harmonics in control input
$M$ Matrix defined to be $D^{-1}(T^TQ + S^T)$
$N_b$ Number of rotor blades
$P_k$ Matrix defined as $(\Delta U_k \Delta U_k^T)^{-1}$

I. Introduction and Background

Stringent requirements for low vibration levels (less than 0.05g) have motivated the development of active control approaches to vibration reduction. The various active control approaches that have been developed were described in Ref. 1. These control approaches fall into two separate categories: (a) active control approaches aimed at reducing vibrations in the rotor before they propagate into the fuselage, and (b) active control approaches implemented in the fuselage using an approach known as active control of structural response (ACSR). Within the first category of active control, where the primary objective is to reduce vibrations in the rotor, two approaches have emerged. These are (1) higher harmonic control (HHC) where the blades are activated in the nonrotating swashplate by introducing pitch commands, and (2) individual blade control (IBC) where each blade can be controlled independently in the rotating frame. Several implementations of IBC are available: (i) the conventional or earliest implementation based on pitch actuation at the blade root in the rotating system, (ii) actively controlled partial-span trailing-edge flaps, and (iii) the active-twist rotor where the entire blade is twisted by piezoelectric fiber embedded in the blade. These approaches are illustrated schematically...
in Fig. 1, and additional description of these approaches can be found in Ref. 1. It is important to note that both HHC as well as IBC active control approaches rely on what is known as the conventional HHC algorithm. Furthermore, even the implementation of the ACSR is based on the HHC algorithm.

Figure 1: An Overview of Active Control Techniques.

One of the most comprehensive overviews of the HHC algorithm and its variants was written by Johnson.\textsuperscript{2} This detailed report provided a history of the development of the algorithm and its implementation in early experimental and numerical studies. A graphical description of the algorithm and its implementation on a helicopter is shown in Fig. 2.

Johnson characterizes the variants of the HHC algorithm as sharing three properties:

1. A linear, quasi-static, frequency-domain model of the helicopter response.
2. The model is identified by a least-squared error or Kalman-filter method. Identification may either be offline (invariant HHC), or online (adaptive HHC).
3. A quadratic-form cost-function is used.

Since this review,\textsuperscript{2} a considerable amount of research on the HHC algorithm has been done, and its application has been extended beyond swashplate-actuated HHC systems to the IBC and ACSR approaches as mentioned earlier. Recent research has largely focused on identification techniques, application of the controller in both open-loop and feedback forms, and the effect of periodic coefficients and nonlinearity that are inherent in the helicopter model.

Of particular note among the many experimental studies performed with this algorithm is the work of Shaw, et al., on the helicopter vibration problem, extending from the 1970s to the late 1980s.\textsuperscript{3–5} Initial open-loop wind-tunnel tests up to $\mu = 0.3$ indicated that the vibratory hub loads were essentially linearly dependent on the harmonic control input, confirming the feasibility of HHC for this application. This was followed by tests in closed-loop using real-time identification of the transfer function. In these studies, three different versions of HHC were considered, each using a different identification procedure: (1) a fixed-gain controller using local linearization of the current vibration levels, (2) a scheduled-gain controller that automatically selected the transfer function matrix based on the current flight condition, and (3) three adaptive HHC controllers that automatically update the transfer matrix. A primary conclusion of this series of tests was that the fixed-gain was highly successful in reducing
vibrations throughout most of the level flight envelope. Shaw\(^5\) also found that measurements of the sensitivity matrix were highly repeatable. Some of Shaw's success may have been due to the fact that vibration sensors were placed in the rotating frame.

Despite this demonstrated success with the simple fixed-gain controller, other studies have observed unstable behavior with invariant HHC.\(^6\) In wind-tunnel tests, gain-scheduled and fixed-gain controllers were shown to saturate the control inputs without achieving any vibration reduction. However, several adaptive variants performed very well.\(^7\) This test also found that open-loop determinations of the sensitivity matrix were not very repeatable, and did not necessarily compare with the sensitivity matrix found by adaptive means.\(^7\) In a later simulation study,\(^8\) Molusis analyzed the effect of nonlinearity on HHC. He attribute the earlier issues with convergence\(^6,7\) to nonlinearity in the system. Multiple minimum solutions were found in several cases, often causing the controller to converge to a false minimum. A nonlinear relationship between HHC input and vibration output was also considered by means of Volterra series.

In conjunction with the aforementioned wind-tunnel tests, flight tests were also performed.\(^9\) An OH-6A helicopter with an HHC system was flown from zero airspeed to 100 knots, using HHC in both open-loop and closed-loop modes. These tests showed significant reduction in helicopter vibrations. However, in transient flight, unsatisfactory results were observed.\(^10\) A HHC system was also flight-tested onboard an SA 349 Gazelle.\(^11\) Both adaptive and fixed gain controllers were found to be quite successful in reducing vibration during flight, and the adaptive technique had success in maneuvering flight. It is interesting to note that the successful HHC wind-tunnel and flight tests were all performed with articulated rotors. A subsequent numerical study found that to implement vibration reduction on a hingeless rotor, significantly higher HHC angles were required, leading to increased blade root moments and pitch link loads.\(^12\)

In an attempt to resolve the apparent discrepancy between the wind-tunnel tests of Shaw et al.\(^3–5\)
and Hammond and Molusis,\textsuperscript{6,7} Nygren and Schrage\textsuperscript{13} conducted a series of numerical simulations with a helicopter aeroelastic response code. This study suggested that fixed-gain control could achieve satisfactory results if the helicopter airspeed were within about 20 knots of the speed at which identification was performed. Constant-thrust maneuvering flight was also studied, where results showed a distinct advantage for adaptive control. The adaptive controller was also found to quickly recover from improper initialization.

Jacklin\textsuperscript{14} has performed an extensive investigation of five system identification algorithms for HHC. The primary focus of the study was to compare several least-squares and Kalman filter techniques. It was found that generally comparable results were obtained, however the Kalman filter methods required a substantial amount of parameter tuning while their least-squares counterpart required much less. The study also found that open-loop identification was the most reliable and could obtain the best vibration reduction results. It was noted that the controller could achieve minimum vibration even before the sensitivity matrix converged to the correct value. Accurate closed-loop identification was found to be more difficult than open-loop identification because the control commands were chosen to control the helicopter vibration rather than to provide excitation. As the vibration approached the minimum value, identification was complicated by the low signal to noise ratio. Probing signals improved the online identification process, however they produced unacceptable vibration increases.

Hall and Wereley\textsuperscript{15} have developed a continuous-time internal-model principle\textsuperscript{16} implementation of HHC, which was shown to be, within first approximation,\textsuperscript{17} identical to the classical "T-matrix" HHC discussed previously. This study dealt only with the non-adaptive (invariant) version of the HHC algorithm. Implementation of this approach required the transfer functions between input and response at different flight conditions; information that can be only obtained experimentally. A similar approach was adopted in Ref. 18, and used for numerical simulations of algorithm stability during vibration reduction.

In parallel to the research performed in the rotorcraft field, an almost identical algorithm was applied in Ref. 19 to the problem of balancing a rotor on magnetic bearings. In this study, they used the term convergent control for the HHC algorithm, in reference to the requirement of achieving a steady-state solution before feeding back information to the controller. Robustness bounds were also explored.

The preceding literature review has highlighted some of the more relevant developments in the history of the HHC algorithm. Recent applied work with this algorithm includes studies of dynamic stall,\textsuperscript{20,21} a highly nonlinear phenomenon, and also actuator saturation.\textsuperscript{22} Notable among these studies is the scarcity of careful examination of this algorithm from a more rigorous control perspective. The primary reasons for the success of the HHC algorithm are due to its relative simplicity, its effectiveness, and, to some extent, its robustness. For general broadband disturbance rejection, there exist fundamental tradeoffs that imply that disturbance reduction over a frequency range entails amplification at other frequencies.\textsuperscript{23} However, in the case where disturbances have specific, known frequencies (tonal disturbances), very high gain can be applied at the frequencies of disturbance, and excellent reduction can be achieved without significant compromises. Thus, this disturbance rejection algorithm is particularly suitable for rotorcraft, because the disturbance is largely tonal, and the frequency of the disturbance is known a priori.

The paper has the objectives outlined below:

1. Provide a development of the HHC algorithm, highlighting modeling assumptions and using a consistent analytical approach.

2. Discuss three versions of the HHC algorithm: (i) the classical, invariant version, (ii) the adaptive version, wherein a recursive least-squares (RLS) method is used for online identification, and (iii) a new relaxed variant.
3. Analyze the robustness of all three versions of HHC, including conditions for stability and convergence. Both additive and multiplicative model uncertainty are considered.

4. Illustrate the use of the above variants of HHC through simulations of helicopter vibration control with an actively controlled flap, and identify differences between the variants.

In achieving these objectives the paper provides a more comprehensive theoretical foundation, from a control perspective, for this successful algorithm while enhancing our understanding of its effectiveness and simplicity.

II. The HHC Algorithm

The HHC algorithm is based on the assumption that the helicopter can be represented by a linear model relating output $z$ to control inputs $u$. In previous studies dealing with a four-bladed rotor,\textsuperscript{1,21,25} the output $z$ consisted of 4/rev vibration levels, while the input vector $u$ contained control inputs at frequencies of 2/rev, 3/rev, 4/rev, and 5/rev components. These relations are illustrated schematically in Fig. 2. Note that the vector $z$ of size $2p \times 2p$ is made up of the sine and cosine components of the $p$ harmonic elements in the output signal $z(t)$. Similarly, the vector $u$ of size $2m \times 2m$ is made up of the sine and cosine components of $m$ harmonic elements in the control input signal $u(t)$.

The HHC algorithm is a frequency-domain approach applied to disturbances (vibrations or noise) having known frequency content that is usually associated with the number of blades and is connected to the blade passage frequency $N_b$/rev. In the HHC algorithm, the measurement of the plant output and update of the control input are not performed continuously, but rather at specific times $t_k = k\tau$, where $\tau$ is the time interval between updates during which the plant output reaches a steady level. In actual implementation of the algorithm, this time interval may be one or more revolutions. During the application of the algorithm, the system is allowed to reach a steady-state (converged) condition, and measures of the vibratory response amplitude and phase are used to determine the amplitude and phase of the required control input signal for vibration reduction.

A diagram of the HHC system as implemented in a helicopter is shown in Fig. 3. With the introduction of a disturbance $w$, representative of the helicopter operating condition, and the observation that system updates are performed at specific times $t_k = k\tau$, the system dynamics are now given by

$$z_k = Tu_k + Ww. \quad (1)$$
In the initial condition, when $k = 0$, this can be written as
\[ z_0 = Tu_0 + Ww. \] (2)

Subtracting Eq. (2) from Eq. (1) to eliminate the unknown $w$ yields
\[ z_k = z_0 + T(u_k - u_0). \] (3)

Equation (3) is referred to by Johnson as the global model of helicopter response.\(^2\) Note that this model depends on the assumption of linearity, and that the sensitivity $T$ (and the starting condition $z_0$) are invariant and known without error either through an identification procedure or direct measurement (offline identification).

The sensitivity $T$ is given by:
\[ T = \frac{\partial z}{\partial u}. \] (4)

The controller is based on a general quadratic cost function
\[ J(z_k, u_k) = z_k^T Q z_k + 2z_k^T S u_k + u_k^T R u_k. \] (5)

However, in most applications, the cross-weighting term in Eq. (5) is neglected and the cost function simplifies to
\[ J(z_k, u_k) = z_k^T Q z_k + u_k^T R u_k. \] (6)

The optimal control law is determined from the requirement
\[ \frac{\partial J(z_k, u_k)}{\partial u_k} = 0, \] (7)
which yields the optimal control law $u_{k,\text{opt}}$, given by
\[ u_{k,\text{opt}} = -(T^T Q T + R)^{-1}(T^T Q)(z_0 - Tu_0). \] (8)

Combining Eqs. (6) and (8), the minimum cost is found to be
\[ J(z_k, u_{k,\text{opt}}) = (z_0 - Tu_0)^T \left[ Q - (QT)D^{-1}(T^T Q) \right] (z_0 - Tu_0), \] (9)

where
\[ D = T^T QT + R \] (10)

This is the most basic version of the HHC algorithm and it yields an explicit relation for optimal control input.

It is also useful to consider another, recursive, form of Eq. (3), where subsequent control steps are written as
\[ z_{k+1} = z_k + T(u_{k+1} - u_k). \] (11)

Note that Eq. (3) is a special case of Eq. (11), where $k = 0$. However, from Eq. (8), $u_{k,\text{opt}}$ is independent of $k$, and remains constant for all future control iterations $k \geq 1$. Equation (11) is referred to by Johnson\(^2\) as the local controller, and it represents a linearization of the response about the current control value.

### A. Example : One-Dimensional Case

To illustrate the algorithm, consider the case where $u$ and $z$ are scalars. Therefore, $J$ is a real function of a real parameter, and $W$ is a scalar. Consider the case $W = 1$, therefore, $J = z^2$. Recall
that the relationship between updates is

\[ z_k = z_{k-1} + \frac{\partial z}{\partial u} (u_k - u_{k-1}) \]  

(12)

then,

\[ \frac{\partial J}{\partial u_i} = 2z_k \frac{\partial z}{\partial u} = 0. \]  

(13)

Since \( \frac{\partial z}{\partial u} \neq 0 \),

\[ z_k = z_{k-1} + \frac{\partial z}{\partial u} (u_k - u_{k-1}) = 0 \]  

(14)

\[ u_{k,\text{opt}} = u_{k-1} - \frac{z_{k-1}}{\frac{\partial z}{\partial u}} \]  

(15)

Which implies that for this case the algorithm is identical to Newton’s method for minimization.

**III. Convergence Analysis**

A recursive form of the optimal control law is developed to demonstrate the one-step convergence property of HHC. Substituting Eq. (8) into Eqs. (5) and (3), the optimal value of \( z_k \) for all \( k \geq 1 \) is given by

\[ z_{k,\text{opt}} = [I - TD^{-1}(T^TQ + S^T)] (z_0 - Tu_0) \]  

(16)

and thus

\[ J(z_{k,\text{opt}}, u_{k,\text{opt}}) = (z_0 - Tu_0)^T [Q - (QT + S)D^{-1}(T^TQ + S^T)] (z_0 - Tu_0). \]  

(17)

These values are attained after the first update.

Using Eq. (3), the optimal control law of Eq. (8) can be expressed recursively as

\[ u_{k+1,\text{opt}} = -D^{-1}(T^TQ + S^T)(z_{k,\text{opt}} - Tu_{k,\text{opt}}). \]  

(18)

The state-space representation of the system dynamics with the optimal control law is

\[
\begin{bmatrix}
  z_{k+1,\text{opt}} \\
  u_{k+1,\text{opt}}
\end{bmatrix}
= A \begin{bmatrix}
  z_{k,\text{opt}} \\
  u_{k,\text{opt}}
\end{bmatrix},
\]

(19)

where \( A \) is a \( 2(p + m) \times 2(p + m) \) matrix defined by

\[
A = \begin{bmatrix}
  I_{2p} - TM & -(I_{2p} - TM)T \\
  -M & MT
\end{bmatrix},
\]

(20)

and \( M \) is a \( 2m \times 2p \) matrix defined by

\[ M = D^{-1}(T^TQ + S^T). \]  

(21)

Note that

\[
A^2 = \begin{bmatrix}
  (I_{2p} - TM)^2 + (I_{2p} - TM)TM & -(I_{2p} - TM)^2T - (I_{2p} - TM)TMT \\
  -M(I_{2p} - TM) - MTM & M(I_{2p} - TM)T + (MT)^2
\end{bmatrix}
\]

(22)

\[
= \begin{bmatrix}
  I_{2p} - TM & -(I_{2p} - TM)T \\
  -M & MT
\end{bmatrix}
= A.
\]

(24)
Hence $A$ is an idempotent matrix (a matrix such that $A^2 = A$), and its eigenvalues are either 0 or 1. To show this, note that $A$ can be decomposed as

$$A = \begin{bmatrix} I_{2p} & T \\ 0 & I_{2m} \end{bmatrix} \begin{bmatrix} I_{2p} & 0 \\ -M & 0_{2m} \end{bmatrix} \begin{bmatrix} I_{2p} & -T \\ 0 & I_{2m} \end{bmatrix},$$

(25)

which implies that the spectral radius of $A$,

$$\max_{1 \leq i \leq n} |\lambda_i| = \text{sprad}(A) = \rho_s(A)$$

(26)

where $A$ has $n$ eigenvalues $\lambda_i$, can be interpreted as the union of $\rho_s(I_{2p})$ and $\rho_s(0_{2m})$:

$$\rho_s(A) = \rho_s(I_{2p}) \cup \rho_s(0_{2m}).$$

(27)

Recall that the eigenvalues of the identity matrix are $\lambda_{I_{2p}} = \{1, \ldots, 1\}$, and for the zero matrix $\lambda_{0_{2m}} = \{0, \ldots, 0\}$. Observing the block structure of the three matrices of Eq. (25), all eigenvalues of the first and third matrix are 1, and eigenvalues of the central matrix must be 0 or 1. With initial conditions $z_0$ and $u_0$, Eq (19) implies that

$$\begin{bmatrix} z_{1,\text{opt}} \\ u_{1,\text{opt}} \end{bmatrix} = A \begin{bmatrix} z_0 \\ u_0 \end{bmatrix},$$

(28)

and

$$\begin{bmatrix} z_{2,\text{opt}} \\ u_{2,\text{opt}} \end{bmatrix} = A \begin{bmatrix} z_{1,\text{opt}} \\ u_{1,\text{opt}} \end{bmatrix} = A^2 \begin{bmatrix} z_0 \\ u_0 \end{bmatrix} = A \begin{bmatrix} z_0 \\ u_0 \end{bmatrix} = \begin{bmatrix} z_{1,\text{opt}} \\ u_{1,\text{opt}} \end{bmatrix}. $$

(29)

Similarly, for all $k = 1, 2, \ldots,$

$$\begin{bmatrix} z_{k,\text{opt}} \\ u_{k,\text{opt}} \end{bmatrix} = A \begin{bmatrix} z_{k-1,\text{opt}} \\ u_{k-1,\text{opt}} \end{bmatrix} = A^2 \begin{bmatrix} z_0 \\ u_0 \end{bmatrix} = \begin{bmatrix} (I - TM)(z_0 - Tu_0) \\ -M(z_0 - Tu_0) \end{bmatrix}. $$

(30)

This confirms the fact that optimum values $u_{k,\text{opt}}$ in Eq. (8) and $z_{k,\text{opt}}$ in Eq. (16) are attained after the first update.

**IV. Robustness of the HHC Algorithm**

The development of the HHC control algorithm assumed that the sensitivity matrix $T$ was known without error. In practical implementation, this is unlikely. Changes in flight condition or nonlinearities can easily cause the system behavior to deviate from this assumption. When $T$ is uncertain, the implementation of HHC with erroneous $T$ can results in degradation of performance and possible instability. If $T$ is not known exactly, and only an estimate $\hat{T}$ of $T$ is given, the control law defined by Eq (18) becomes:

$$\hat{u}_{k+1} = -\hat{M}(z_k - T\hat{u}_k),$$

(31)

where

$$\hat{M} = \hat{D}^{-1}(T^TQ + S^T)$$

(32)
In order to develop a condition for the stability of the algorithm, a state-space representation of the system-dynamics must be introduced, from Eq. (31),

\[
\begin{bmatrix}
    z_{k+1} \\
    \hat{u}_{k+1}
\end{bmatrix} = \hat{A} \begin{bmatrix}
    z_k \\
    \hat{u}_k
\end{bmatrix},
\]

(33)

where \(\hat{A}\) is defined by

\[
\hat{A} = \begin{bmatrix}
    (I_{2p} - T\hat{M}) & T(M\hat{T} - I_{2p}) \\
    -\hat{M} & \hat{M}\hat{T}
\end{bmatrix}
\]

(34)

and \(\Delta T = \hat{T} - T\).

It is useful to factor \(\hat{A}\) as

\[
\hat{A} = \begin{bmatrix}
    I_{2p} & T \\
    0 & I_{2m}
\end{bmatrix} \begin{bmatrix}
    I_{2p} & 0 \\
    -\hat{M} & \hat{M}\Delta T
\end{bmatrix} \begin{bmatrix}
    I_{2p} & -T \\
    0 & I_{2m}
\end{bmatrix},
\]

(35)

which shows that

\[
\max_{1 \leq i \leq n} |(\lambda_{\hat{A}})_i| = \rho_s(\hat{A}) = \rho_s(I_{2p}) \cup \rho_s(\hat{M}\Delta T).
\]

(36)

Equation (36) yields insight on the stability of the system. Note that stability of the algorithm requires that the eigenvalues of \(\hat{M}\Delta T\) be such that:

\[
\max_{1 \leq i \leq n} |(\lambda_{\hat{M}\Delta T})_i| = \rho_s(\hat{M}\Delta T) < 1.
\]

(37)

Using Eq. (6), the spectral radius \(\rho_s(\hat{M}\Delta T)\) can be evaluated, if an operator \(\sigma_{\max}\) is defined as the largest singular value of the matrix \(A\)

\[
\sigma_{\max}(A) = \max_{1 \leq i \leq n} \left(\sqrt{(A^*A)_i}\right)
\]

(38)

where \(A^*\) is the adjoint or conjugate-transpose matrix of \(A\), \(A^* = (\hat{A})^T\). Similarly, an operator \(\sigma_{\min}\) can be defined as the smallest singular value of matrix. Using these operators to expand the stability condition,

\[
\rho_s(\hat{M}\Delta T) \leq \rho_s(T^TQT + R)^{-1}T^TQ\Delta T
\]

\[
\leq \sigma_{\max}(T^TQT + R)^{-1}T^TQ\Delta T
\]

\[
\leq \frac{\sigma_{\max}(T)\sigma_{\max}(Q)\sigma_{\min}(\Delta T)}{\sigma_{\min}(T) + \sigma_{\max}(\Delta T)}
\]

\[
\leq \frac{\sigma_{\max}(T)\sigma_{\max}(Q)}{\sigma_{\min}(R)}
\]

(39)

and it can be shown that, if

\[
\sigma_{\max}(\Delta T) < \frac{-\sigma_{\max}(T)}{2} + \frac{1}{2} \sqrt{\sigma_{\max}(T)^2 + \frac{4\sigma_{\min}(R)}{\sigma_{\max}(Q)}},
\]

(40)

then \(\text{sprad}(\hat{M}\Delta T) < 1\). The matrix \(Q\) consists of weights on the parameters to be reduced (such as vibration or noise levels) while the matrix \(R\) consists of weights on the control inputs (such as flap deflections). If \(\frac{\sigma_{\min}(R)}{\sigma_{\max}(Q)}\) is large (minimum energy control), then according to Eq. (40), HHC control possesses a high degree of robustness and a sufficient condition for the stability of HHC algorithm is...
approximately given by:
\[
\sigma_{\text{max}}(\Delta T) < \sqrt{\frac{\sigma_{\text{min}}(R)}{\sigma_{\text{max}}(Q)}}. \tag{41}
\]

However, if \(\frac{\sigma_{\text{min}}(R)}{\sigma_{\text{max}}(Q)}\) is small (cheap control), then Eq. (40) implies that robustness is somewhat compromised.

The explicit stability condition of Eq. (41) lends insight into the behavior of the algorithm. In a later section of this paper it will be shown that the algorithm can be made stable even in situations where \(T\) varies significantly.

The preceding analysis has shown that the stability of the algorithm depends on the degree to which \(T\) is correctly estimated, or the choice of control weightings \(Q\) and \(R\). The behavior of the objective function \(J\) has not yet been considered. That is, even if the algorithm is stable, having only an estimate of \(T\) may affect the attainable minimum. Thus, a convergence analysis is required. Consider Eq. (35), which can be extended to show
\[
\hat{A}^k = \begin{bmatrix} I_{2p} & T \\ 0 & I_{2m} \end{bmatrix} \begin{bmatrix} I & 0 \\ -\sum_{i=1}^{k-1} (\hat{M}\Delta T)^i \hat{M} & (\hat{M}\Delta T)^k \end{bmatrix} \begin{bmatrix} I_{2p} & -T \\ 0 & I_{2m} \end{bmatrix} \tag{42}
\]

Now it is assumed that HHC is stable, that is, Eq. (37) is satisfied. In this case,
\[
\lim_{k \to \infty} (\hat{M}\Delta T)^k = 0 \tag{43}
\]
and one can define a matrix \(\Gamma_s\) such that
\[
\Gamma_s = \lim_{k \to \infty} \sum_{i=1}^{k-1} (\hat{M}\Delta T)^i = (I - \hat{M}\Delta T)^{-1}. \tag{44}
\]

Hence Eqs. (42), (43) and (44) imply that
\[
\lim_{k \to \infty} \hat{A}^k = \begin{bmatrix} I - \hat{T}\Gamma_s M & \hat{T}(\Gamma_s MT - I) \\ -\hat{\Gamma}_s M & \hat{\Gamma}_s MT \end{bmatrix} \tag{45}
\]

The limiting values of \(z_k\) and \(\hat{u}_k\) are given by
\[
\lim_{k \to \infty} \begin{bmatrix} z_k \\ \hat{u}_k \end{bmatrix} = \lim_{k \to \infty} \hat{A}^k \begin{bmatrix} z_0 \\ \hat{u}_0 \end{bmatrix} = \begin{bmatrix} (I - \hat{T}\Gamma_s \hat{M})(z_0 - \hat{T}\hat{u}_0) \\ -\hat{\Gamma}_s \hat{M}(z_0 - \hat{T}\hat{u}_0) \end{bmatrix}. \tag{46}
\]

Next, define the limiting cost \(J_{T,\infty}\) by
\[
J_{T,\infty} = \lim_{k \to \infty} J(z_k, \hat{u}_k). \tag{47}
\]

Substituting Eq. (46) into Eq. (5) yields
\[
J_{T,\infty} = (z_0 - \hat{T}\hat{u}_0)^T \begin{bmatrix} Q - \hat{Q}\Gamma_s \hat{M} - (\hat{Q}\Gamma_s \hat{M})^T + \hat{M}^T\Gamma_s MT\hat{\Gamma}_s \hat{M} \end{bmatrix} (z_0 - \hat{T}\hat{u}_0). \tag{48}
\]

Note that
\[
(D^{-1/2}T^TQ - D^{1/2}\Gamma_s \hat{M})^T(D^{-1/2}T^TQ - D^{1/2}\Gamma_s \hat{M}) \geq 0, \tag{49}
\]
and hence
\[ \text{QTD}^{-1}T^TQ \geq \text{QTT}_s\hat{\mathbf{M}} + (\text{QTT}_s\hat{\mathbf{M}})^T - \hat{\mathbf{M}}^T\hat{\Gamma}_s^TD\hat{\Gamma}_s\hat{\mathbf{M}}. \] (50)

Assuming \( \hat{u}_0 = u_0 \), Eqs. (48), (50) and Eq. (9) yield
\[ J_{T,\infty} \geq J(z, u_{k,\text{opt}}), \] (51)
which confirms the expected fact that the performance is not better than the optimal performance obtained when \( T \) is exactly known.

Now, consider the case where the estimated value \( \hat{T} \) of \( T \) involves a multiplicative error, that is,
\[ \hat{T} = T(I + \Delta T_{\text{mul}}), \] (52)
where \( \Delta T \) is a \( 2m \times 2m \) matrix. Then \( \hat{T} \) can be expressed equivalently by \( \hat{T} = T + \Delta T \), where
\[ \Delta T = T\Delta T_{\text{mul}}. \] (53)

A sufficient condition for stability of HHC is
\[ \rho_s(\hat{\mathbf{M}}\Delta T_{\text{mul}}) < 1. \] (54)

Substituting Eq. (53) into Eq. (39) yields
\[ \rho_s(\hat{\mathbf{M}}T\Delta T_{\text{mul}}) = \rho_s\left( (T^T\text{QT} + R)^{-1}T^T\text{QT}\Delta T_{\text{mul}} \right) \]
\[ \leq \frac{\sigma_{\text{max}}^2(T)\sigma_{\text{max}}(Q)\sigma_{\text{max}}(\Delta T_{\text{mul}})(\sigma_{\text{max}}(\Delta T_{\text{mul}}) + 1)}{\sigma_{\text{min}}(R)}. \] (55)

Finally, it can be shown that the HHC algorithm is stable if
\[ \sigma_{\text{max}}(\Delta T_{\text{mul}}) < \frac{1}{2} + \frac{1}{2}\sqrt{1 + \frac{4\sigma_{\text{min}}(R)}{\sigma_{\text{max}}^2(T)\sigma_{\text{max}}(Q)}}. \] (56)

V. Relaxed HHC for Enhanced Robustness

A promising alternative to conventional HHC is designated “relaxed HHC”, where a relaxation coefficient is introduced into the algorithm. This technique was pioneered by Depailler\textsuperscript{24} and mentioned in a computer program user’s manual, but never fully developed. This variation on the HHC algorithm has proved itself useful under highly nonlinear condition induced by dynamic stall, where any estimate of \( T \) is uncertain. This variant of the algorithm compromises the one-step convergence property of the algorithm shown earlier, but improves robustness. Recall that when \( T \) is known, the optimal control law \( u_{k+1} \) from Eq. (18) can be expressed as:
\[ u_{k+1} = u_k + \Delta u_k, \] (57)
where one can define
\[ \Delta u_k = -Mz_k + (MT - I)u_k. \] (58)
Replacing \( \Delta u_k \) in Eq. (57) by \( \alpha \Delta u_{k,\alpha} \), yields the relaxed control update law,
\[ u_{k+1,\alpha} = u_{k,\alpha} + \alpha \Delta u_{k,\alpha}. \] (59)

AMERICAN INSTITUTE OF AERONAUTICS AND ASTRONAUTICS
where \( u_{0,\alpha} = u_0 \). In this case, the state-space representation is given by

\[
\begin{bmatrix}
    z_{k+1} \\
    u_{k+1,\alpha}
\end{bmatrix} = A_\alpha \begin{bmatrix}
    z_k \\
    u_{k,\alpha}
\end{bmatrix},
\]

where the following definition is used,

\[
A_\alpha = \begin{bmatrix}
    I - \alpha TM & -(I - \alpha TM)T + (1 - \alpha)T \\
    -\alpha M & \alpha MT + (1 - \alpha)I
\end{bmatrix}.
\]  

(60)

Note that for \( \alpha = 1 \), \( A_1 = A \). The matrix \( A_\alpha \) can be factored as

\[
A_\alpha = \begin{bmatrix}
    I_{2p} & T \\
    0 & I_{2m}
\end{bmatrix} \begin{bmatrix}
    I_{2p} & 0 \\
    -\alpha M & (1 - \alpha)I_{2m}
\end{bmatrix} \begin{bmatrix}
    I_{2p} & -T \\
    0 & I_{2m}
\end{bmatrix},
\]

(61)

which implies

\[
\max_{1 \leq i \leq n} |(\lambda_{A_\alpha})_i| = \rho_s(A_\alpha) = \rho_s(I_{2p}) \cup \rho_s((1 - \alpha)I_{2m}).
\]  

(62)

To analyze Eq. (64), assume that \( 0 < \alpha < 2 \). In any practical case, \( \alpha < 1 \), as the step size is reduced by multiplying by the factor \( \alpha \). This assumption allows the evaluation of the limits

\[
\lim_{k \to \infty} \alpha \left( \sum_{i=1}^{k} (1 - \alpha)^{i-1} \right) = 1,
\]  

(63)

and

\[
\lim_{k \to \infty} (1 - \alpha)^k = 0,
\]  

(64)

hence it follows from Eqs. (64) - (66) that

\[
\lim_{k \to \infty} A^k_\alpha = A,
\]  

(65)

and the steady-state values of \( z_k \) and \( u_{k,\alpha} \) are given by

\[
\lim_{k \to \infty} \begin{bmatrix}
    z_k \\
    u_{k,\alpha}
\end{bmatrix} = \lim_{k \to \infty} A^k_\alpha \begin{bmatrix}
    z_0 \\
    u_0
\end{bmatrix} = \begin{bmatrix}
    z_{opt} \\
    u_{opt}
\end{bmatrix}.
\]  

(66)

Again, one has to compare the final value of the objective function with its value without the relaxed control. To do so, define the limiting cost \( J_{T,\alpha,\infty} \) as

\[
J_{T,\alpha,\infty} = \lim_{k \to \infty} J(z_k, u_{k,\alpha}).
\]  

(67)

It thus follows from Eqs. (68) and (9) that

\[
J_{T,\alpha,\infty} = J(z, u_{opt}).
\]  

(68)
Hence, the steady-state values of $z_k$ and $u_k$ for the relaxed HHC algorithm are the same as the optimal values obtained in a single step using conventional HHC.

Relaxed HHC is only useful in the cases where $T$ is uncertain (it increases convergence time in all other scenarios), and thus it is useful to perform a robustness analysis in the presence of relaxed control, following the procedure described in the previous section. When only an estimate $\hat{T}$ of the sensitivity is known, the relaxed HHC update law is given by

$$u_{k+1,\alpha} = \hat{u}_{k,\alpha} + \alpha \Delta u_{k,\alpha},$$

(71)

where $\Delta u_{k,\alpha}$ is defined by

$$\Delta u_k = -Mz_k + (\hat{M}T - I)\hat{u}_{k,\alpha},$$

(72)

and $\hat{u}_{0,\alpha} = u_0$. The state-space representation of the system dynamics is given by

$$\begin{bmatrix} z_{k+1} \\ \hat{u}_{k+1,\alpha} \end{bmatrix} = \hat{A}_\alpha \begin{bmatrix} z_k \\ \hat{u}_{k,\alpha} \end{bmatrix},$$

(73)

where $\hat{A}_\alpha$ is defined by

$$\hat{A}_\alpha = \begin{bmatrix} I - \alpha T\hat{M} & -\alpha T(\hat{M}T - I_{2p}) \\ -\alpha M & \alpha MT + (1 - \alpha)I \end{bmatrix}.$$

(74)

The matrix $\hat{A}_\alpha$ can be factored as

$$\hat{A}_\alpha = \begin{bmatrix} I_{2p} & T \\ 0 & I_{2m} \end{bmatrix} \begin{bmatrix} I_{2p} & 0 \\ -\alpha M & \alpha M\Delta T + (1 - \alpha)I_{2m} \end{bmatrix} \begin{bmatrix} I_{2p} & -T \\ 0 & I_{2m} \end{bmatrix},$$

(75)

where $\Delta T = \hat{T} - T$. It follows from (75) that

$$\text{spec}(\hat{A}_\alpha) = \text{spec}(I_{2p}) \cup \text{spec}(\alpha M\Delta T + (1 - \alpha)I_{2m}).$$

(76)

Hence the relaxed HHC algorithm is stable if and only if

$$\rho_s(\alpha M\Delta T + (1 - \alpha)I_{2m}) < 1.$$  

(77)

Next, consider the eigenvalues of $(\hat{M}\Delta T)$,

$$\text{spec}(\hat{M}\Delta T) = \{\lambda_1, \ldots, \lambda_{2m}\}$$

(78)

such that the eigenvalues of the matrix $(\alpha M\Delta T + (1 - \alpha)I_{2m})$ can be written as

$$\text{spec}(\alpha M\Delta T + (1 - \alpha)I_{2m}) = \{\lambda_{a_1}, \ldots, \lambda_{a_{2m}}\},$$

(79)

where, for all $i = 1, \ldots, 2m$,

$$\lambda_{ai} = \alpha \lambda_i + 1 - \alpha.$$  

(80)

Hence Eq. (80) implies that

$$|\lambda_{ai}|^2 = 1 + \alpha^2(\sigma_i - 1)^2 + 2\alpha(\sigma_i - 1) + \alpha^2\iota_i^2,$$

(81)

where $\sigma_i = \text{Re}(\lambda_i)$ and $\iota_i = \text{Im}(\lambda_i)$ such that $\lambda_i = \sigma_i + \iota_i$. Next, define $\Lambda_{\min}$ and $\Lambda_{\max}$ as the minimum
and maximum real part of the eigenvalues of \((\alpha \hat{M} \Delta T + (1 - \alpha)I_{2m})\) by

\[
\Lambda_{\text{min}} = \min_{i=1, \ldots, 2m} \sigma_i
\]

and

\[
\Lambda_{\text{max}} = \max_{i=1, \ldots, 2m} \sigma_i.
\]

Assuming \(\Lambda_{\text{max}} < 1\), it follows that, for \(i = 1, \ldots, 2m\),

\[
\sigma_i < 1.
\]

Hence it follows from Eqs. (81) and (84) that if

\[
0 \leq \alpha < \frac{2(1 - \sigma_i)}{(1 - \sigma_i)^2 + (\xi_i)^2},
\]

then \(|\lambda_{\alpha_i}| < 1\). Define

\[
\alpha_{\text{max}} = \min_{i=1, \ldots, 2m} \frac{2(1 - \sigma_i)}{(1 - \sigma_i)^2 + (\xi_i)^2}.
\]

Hence for all \(0 \leq \alpha < \alpha_{\text{max}}\), and \(i = 1, \ldots, 2m\), it follows from (85)-(86) that

\[
|\lambda_{\alpha_i}| < 1
\]

and it follows from Eq. (79) that the condition of Eq. (77) is satisfied.

Alternatively if \(\Lambda_{\text{min}} > 1\), then, for all \(i = 1, \ldots, 2m\),

\[
\sigma_i > 1.
\]

Hence (88) and (81) imply that if

\[
\frac{2(1 - \sigma_i)}{(1 - \sigma_i)^2 + (\xi_i)^2} < \alpha \leq 0,
\]

then

\[
|\lambda_{\alpha_i}| < 1.
\]

Define

\[
\alpha_{\text{min}} = \max_{i=1, \ldots, 2m} \frac{2(1 - \sigma_i)}{(1 - \sigma_i)^2 + (\xi_i)^2}.
\]

Hence for all \(\alpha_{\text{min}} < \alpha \leq 0\), and \(i = 1, \ldots, 2m\), it follows from (89)-(91) that

\[
|\lambda_{\alpha_i}| < 1
\]

and finally it follows from Eq. (79) that Eq. (77) is once again satisfied. Hence if either \(\Lambda_{\text{max}} < 1\) or \(\Lambda_{\text{min}} > 1\), then, there exists \(\alpha\) such that stability of relaxed HHC control can be guaranteed.
Note that
\[
\tilde{A}_\alpha^k = \begin{bmatrix}
I & 0 \\
0 & I_{2m}
\end{bmatrix} \begin{bmatrix}
\mathbf{I} & 0 \\
-\alpha \sum_{i=1}^{k-1} (\alpha \tilde{M} \Delta T + (1 - \alpha) \mathbf{1})^i \tilde{M} (\alpha \tilde{M} \Delta T + (1 - \alpha) \mathbf{1})^k
\end{bmatrix} \begin{bmatrix}
I_{2p} & -T \\
0 & I_{2m}
\end{bmatrix}.
\] (93)

Assuming \(\alpha\) is chosen so that Eq. (77) is satisfied, it follows that
\[
\lim_{k \to \infty} (\alpha \tilde{M} \Delta T + (1 - \alpha) \mathbf{1})^k = 0,
\] (94)
and
\[
\lim_{k \to \infty} \sum_{i=1}^{k-1} (\alpha \tilde{M} \Delta T + (1 - \alpha) \mathbf{1})^i = (\mathbf{I} - \alpha \tilde{M} \Delta T - (1 - \alpha) \mathbf{1})^{-1} = \frac{1}{\alpha} \Gamma_s,
\] (95)
where \(\Gamma_s\) is defined in Eq. (44). Hence from Eqs. (93) - (95), it follows that
\[
\lim_{k \to \infty} \tilde{A}_\alpha^k = \begin{bmatrix}
\mathbf{I} - TN\tilde{M} & T(\Gamma_s \tilde{M} T - \mathbf{1}) \\
-\Gamma_s \tilde{M} & \Gamma_s \tilde{M} \end{bmatrix}.
\] (96)

If Eq. (37) is satisfied, then comparing Eq. (45) and Eq. (96) yields
\[
\lim_{k \to \infty} \tilde{A}_\alpha^k = \lim_{k \to \infty} \tilde{A}^k,
\] (97)
and hence using Eq. (46), the steady-state values of \(z_k\) and \(\hat{u}_{k, \alpha}\) are given by
\[
\lim_{k \to \infty} \begin{bmatrix}
z_k \\
\hat{u}_{k, \alpha}
\end{bmatrix} = \lim_{k \to \infty} \tilde{A}_\alpha^k \begin{bmatrix}
z_0 \\
\hat{u}_0
\end{bmatrix} = \lim_{k \to \infty} \tilde{A}^k \begin{bmatrix}
z_0 \\
\hat{u}_0
\end{bmatrix} = \begin{bmatrix}
(I - TN\tilde{M})(z_0 - Tu_0) \\
-\Gamma_s \tilde{M}(z_0 - Tu_0)
\end{bmatrix}.
\] (98)

Define the limiting cost \(J_{T, \alpha, \infty}\) by
\[
J_{T, \alpha, \infty} = \lim_{k \to \infty} J(z_k, \hat{u}_{k, \alpha}).
\] (99)
Assuming (37) is satisfied, implies that \(J_{T, \infty}\) exists and it follows from (98) and (51) that
\[
J_{T, \alpha, \infty} = J_{T, \infty} \geq J(z, u_{\text{opt}}),
\] (100)
Hence if \(\Delta T\) satisfies the condition of Eq. (37), and that of Eq. (77) for an appropriate \(\alpha\), then the limiting value of the objective function obtained using HHC control and relaxed HHC control are the same.

### VI. Adaptive Control

Another alternative version of the HHC algorithm is also available, known as adaptive or recursive HHC, and it was discussed in Ref. 2. In this version, the sensitivity \(T\) is identified online, and is used to implement an adaptive extension of HHC. To pursue this, relative parameters are defined, \(\Delta z_k\), with length \(2p\) and \(\Delta u_k\) with length \(2m\) by
\[
\Delta z_k = z_k - z_{k-1}, \quad \Delta u_k = u_k - u_{k-1},
\] (101)
and, $\Delta Z_k$ of size $2p \times k$ and $\Delta U_k$ of size $2m \times k$ by

$$
\Delta Z_k = \begin{bmatrix} \Delta z_1 & \cdots & \Delta z_k \end{bmatrix}, \quad \Delta U_k = \begin{bmatrix} \Delta u_1 & \cdots & \Delta u_k \end{bmatrix}.
$$

(102)

The relation between the successive updates of vibration levels $z_k$ is

$$
z_{k+1} = z_k + T(u_{k+1} - u_k).
$$

(103)

This can be represented in another form,

$$
\Delta z_k = T \Delta u_k.
$$

(104)

Hence, it follows from Eqs. (104) and (101) that

$$
\Delta Z_k = T \Delta U_k.
$$

(105)

Assuming $\Delta U_k \Delta U_k^T$ is nonsingular, one can define

$$
P_k = (\Delta U_k \Delta U_k^T)^{-1},
$$

(106)

and from Eq. (105) the least squares estimate $\hat{T}_{LS_k}$ of $T$ is given by

$$
\hat{T}_{LS_k} = \Delta Z_k \Delta U_k^T P_k.
$$

(107)

The recursive least squares method is used to iteratively update $\hat{T}_{LS_k}$ based on the past and current values of $\Delta z_k$ and $\Delta u_k$. From Eq. (106), it follows that

$$
P_{k+1}^{-1} = \Delta U_{k+1} \Delta U_{k+1}^T = \sum_{i=1}^{k+1} \Delta u_i \Delta u_i^T
$$

$$
= \sum_{i=1}^{k} \Delta u_i \Delta u_i^T + \Delta u_{k+1} \Delta u_{k+1}^T
$$

$$
= P_k^{-1} + \Delta u_{k+1} \Delta u_{k+1}^T,
$$

(108)

rewriting Eq. (107) as

$$
\hat{T}_{LS_k} = \left( \sum_{i=1}^{k} \Delta z_i \Delta u_i^T \right) P_k,
$$

(109)

and replacing $k$ by $k + 1$ in Eq. (109) yields

$$
\hat{T}_{LS_{k+1}} = \left( \sum_{i=1}^{k+1} \Delta z_i \Delta u_i^T \right) P_{k+1} = \left( \sum_{i=1}^{k} \Delta z_i \Delta u_i^T + \Delta z_{k+1} \Delta u_{k+1}^T \right) P_{k+1}.
$$

(110)

Hence substituting $P_{k+1}^{-1}$ from Eq. (108) into Eq. (109) yields

$$
\sum_{i=1}^{k} \Delta z_i \Delta u_i^T = \hat{T}_{LS_k} \left( P_{k+1}^{-1} - \Delta u_{k+1} \Delta u_{k+1}^T \right).
$$

(111)
Substituting Eq. (111) into Eq. (110) yields
\[ T_{LS_{k+1}} = \left[ T_{LS_k} (P_{k+1}^{-1} - \Delta u_{k+1} \Delta u_{k+1}^T) + \Delta z_{k+1} \Delta u_{k+1}^T \right] P_{k+1} \]
\[ = T_{LS_k} + \left[ \Delta z_{k+1} - T_{LS_k} \Delta u_{k+1} \right] \Delta u_{k+1}^T P_{k+1} \]
\[ = T_{LS_k} + \varepsilon_{k+1} K_{k+1}, \]
(112)
(113)
(114)
where
\[ \varepsilon_{k+1} = \Delta z_{k+1} - T_{LS_k} \Delta u_{k+1} \]
(115)
and
\[ K_{k+1} = \Delta u_{k+1}^T P_{k+1}. \]
(116)

Using the matrix inversion lemma in Eq. (108),\(^26\) \( P_{k+1} \) can be expressed recursively as
\[ P_{k+1} = P_k - P_k \Delta u_{k+1} (1 + \Delta u_{k+1}^T P_k \Delta u_{k+1})^{-1} \Delta u_{k+1}^T P_k. \]
(117)
Combining Eqs. (116) and (117) yields
\[ K_{k+1} = \Delta u_{k+1}^T P_k (1 + \Delta u_{k+1}^T P_k \Delta u_{k+1})^{-1}. \]
(118)

Since \( u_k u_k^T \) is positive semi-definite for all \( k \), Eq. (108) implies that if \( \Delta U_k \Delta U_k^T \) is nonsingular, then \( \Delta U_k \Delta U_k^T \) is nonsingular for all \( k > k_0 \). Hence the recursive procedure to determine \( T_{LS_k} \) for all \( k > k_0 \) is given by
\[ K_{k+1} = (1 + \Delta u_{k+1}^T P_k \Delta u_{k+1})^{-1} \Delta u_{k+1}^T P_k, \]
\[ T_{LS_{k+1}} = T_{LS_k} + \varepsilon_{k+1} K_{k+1}, \]
\[ P_{k+1} = P_k (I - \Delta u_{k+1} K_{k+1}). \]
(119)
(120)
(121)

Note that
\[ \text{rank}(\Delta U_k \Delta U_k^T) = \text{rank}(\Delta U_k) \leq \min(k, 2m). \]
(122)
Since \( \Delta U_k \Delta U_k^T \) is \( 2m \times 2m \), it follows from (122) that \( \Delta U_k \Delta U_k^T \) is singular for all \( k < 2m \). Hence the recursive procedure (119)-(121) cannot be used for \( k < 2m \).

A suboptimal approach to determining an estimate \( \hat{T}_k \) of \( T \) is to replace \( P_k \) in Eqs. (119)-(121) by \( \hat{P}_k \), that is
\[ K_{k+1} = (1 + \Delta u_{k+1}^T \hat{P}_k \Delta u_{k+1})^{-1} \Delta u_{k+1}^T \hat{P}_k, \]
\[ \hat{T}_{k+1} = \hat{T}_k + \varepsilon_{k+1} K_{k+1}, \]
\[ \hat{P}_{k+1} = \hat{P}_k (I - \Delta u_{k+1} K_{k+1}). \]
(123)
(124)
(125)
where \( \hat{P}_0 \) is positive definite but otherwise arbitrary. It follows from Eqs. (123)-(125) that \( \hat{P}_k \) is positive definite for all \( k \geq 0 \) and is given by
\[ \hat{P}_k = (\hat{P}_0^{-1} + \Delta U_k \Delta U_k^T)^{-1}. \]
(126)
Furthermore \( \hat{T}_k \) is given by
\[ \hat{T}_k = \Delta z_k \Delta U_k^T (\hat{P}_0^{-1} + \Delta U_k \Delta U_k^T)^{-1}. \]
(127)

18
AMERICAN INSTITUTE OF AERONAUTICS AND ASTRONAUTICS
In this approach, since \( \hat{P}_0 \) is positive definite, the inverse in Eq. (127) always exists, and hence the recursive procedure can be used for all \( k \geq 0 \). The updated estimate \( \hat{T}_k \) is used at each control update step to calculate the control law \( u_{k+1} \), which is given by

\[
 u_{k+1} = -M_k (z_k - \hat{T}_k u_k), \tag{128}
\]

where \( M_k \) is defined by

\[
 M_k = (T_k^T Q T_k + S^T T_k + T_k^T S + R)^{-1} (T_k^T Q + S^T). \tag{129}
\]

Assuming \( (\Delta U_k \Delta U_k^T)^{-1} \) exists, it follows from (126) that if \( \hat{P}_0 \to \infty \) then \( \hat{P}_k \to (\Delta U_k \Delta U_k^T)^{-1} \) and hence Eqs. (127) and (107) imply that \( \hat{T}_k \to \hat{T}_{LS_k} \).

A convergence analysis for adaptive HHC is provided in Appendix A.

**VII. Illustrative Results**

A representative numerical study was performed to evaluate the use of the relaxation factor in highly nonlinear flight conditions, when the conventional invariant version of HHC is unable to reduce vibrations. Simulations are also performed where the initial identification of the sensitivity matrix \( T \) is poor, to judge controller response.

**A. Description of Simulation**

An aeroelastic code, described in Refs. 21, 24 and 25, was used to perform simulations on a helicopter that resembles an MBB BO-105 flying with an advance ratio of \( \mu = 0.15 \). This is an advance ratio where the largest amount of blade-vortex interaction (BVI) is experienced, inducing high levels of vibration and noise. Two flight conditions at the same advance ratio were considered, (1) a condition corresponding to \( 6^\circ \) descending flight in heavy BVI, and (2) level flight where BVI effects are reduced. Most of the results presented are for the descending flight case where the degree of nonlinearity is larger.

Vibration reduction is achieved by means of a single actively-controlled flap (ACFs) located on each blade, see Fig. 1. The control input vector \( u_k \) consists of sine and cosine components of \( 2/\text{rev}, 3/\text{rev}, 4/\text{rev}, \) and \( 5/\text{rev} \) harmonics. The vector \( z_k \) consists of the sine and cosine components of the six \( 4/\text{rev} \) hub shears and moments. Thus, \( u_k \) has size \( 2m = 8 \), while \( z_k \) has size \( 2p = 12 \).

The aeroelastic response code computes steady-state solutions in several steps, typically 8-12 steps are required to reach a converged solution. The HHC algorithm requires that a steady-state be reached between control updates, as described earlier in this paper. To determine the effect of a poorly estimated T-matrix on HHC, only one simulation step is used in the identification process instead of the typical 8-12. This results in a T-matrix with error that does not strictly correspond to the additive or multiplicative error types used in convergence analysis described earlier in this paper. However, this error can represent real-time measurement error experienced on an actual helicopter.

Both invariant and adaptive HHC algorithms are considered. The rotor response is calculated by first finding the trim condition, then proceeding to system identification. The T-matrix is identified before closed-loop control is engaged for both the invariant and adaptive HHC algorithms. Following trim and identification, closed-loop control is turned on, with updates between every 8-12 simulation steps to allow the system to return to a steady-state. The simulation is allowed to proceed for 10-25 control updates and the cost function \( J \) is tracked. A representative plot of the changes in the
nondimensional 4/rev vertical hub shear during this process is shown in Fig. 4, for the level flight case.

The primary goal here is to quantify the effect of the relaxation factor on robustness. Four categories of simulations were performed, classical invariant HHC with both good and poor estimates of $T$, and adaptive HHC with both good and poor estimates of $T$. For each of these cases, the relaxation coefficient was varied from $\alpha = 0.1$ to $\alpha = 1.0$ (unrelaxed control), resulting in a total of forty simulations. The relaxed adaptive variant is implemented with the same update rule as for the invariant case:

$$u_{k+1,\alpha} = u_{k,\alpha} + \alpha \Delta u_{k,\alpha},$$

An analytic robustness and convergence analysis of relaxed adaptive HHC is not considered at this time. An exponential window is also implemented for adaptive control. The exponential window acts as a “forgetting factor,” emphasizing the more current data:

$$F_f = \gamma_f^k,$$

where $\gamma_f$ is the exponential window parameter varying $0 < \gamma_f < 1$, with $\gamma_f = 0.8$ used in this study. This is implemented by modifying Eqs. (123)-(125) with Eq. (130):

$$K_{k+1} = \left( \gamma_f^k + \Delta u_{k+1}^T \hat{P}_k \Delta u_{k+1} \right)^{-1} \Delta u_{k+1}^T \hat{P}_k,$$

$$T_{k+1} = T_k + \varepsilon_{k+1} K_{k+1},$$

$$\hat{P}_{k+1} = \hat{P}_k \left( \frac{1}{\gamma_f^k} I - \Delta u_{k+1} K_{k+1} \right),$$

**B. Simulated Results**

The adaptive and classical variants of HHC are compared in Fig. 5 over the range of relaxation coefficients $\alpha = 0.1$ to $\alpha = 1.0$ for the descending flight case. When $\alpha = 1.0$ (unrelaxed control), the invariant algorithm fails to converge to the optimal value of the objective function, probably due to the operating nonlinearities of the descending flight condition. However, the adaptive algorithm achieves a near-optimal value in only five control updates. As the relaxation factor $\alpha$ is reduced, the classical (invariant) algorithm displays consistently improving convergence to the desired minimum.
Figure 5: Comparison of Adaptive and Classical HHC Algorithms When T is Well Identified
Figure 6 illustrates the effect of poor estimation of the T-matrix using the procedure outlined earlier, also for the descending flight case. In this case, the invariant algorithm is never stable, not even with a relaxation coefficient of $\alpha = 0.1$. The adaptive algorithm displays problems achieving good minimum solutions. In the unrelaxed adaptive case, no vibration reduction is archived. This highlights the importance of achieving steady-state solutions between control updates. With the relaxation factor introduced at $\alpha = 0.1$, the adaptive algorithm does approach the minimum in a stable, albeit slow, manner.

The effect of the flight condition on controller stability is shown in Fig. 7. Two conditions are shown: (1) the $6^\circ$ descent case discussed previously and (2) a simplified level flight case. It is seen that the unrelaxed invariant HHC algorithm achieves good vibration reduction for the level flight case. The adaptive variant also performs well. These results confirm experimental observations on fixed-gain HHC effectiveness.

VIII. Concluding Remarks

This paper has summarized the basic features of the HHC algorithm that has been in wide usage for active vibration reduction on helicopter rotors in forward flight. Subsequently, the convergence and robustness characteristics of a number of variants of the algorithm are examined. Furthermore, a new relaxed version of the algorithm is introduced and it is shown that the relaxation coefficient has a major effect on the performance of the algorithm. Figure 8 presents an overview of the different variants of the HHC algorithm which facilitates a unified view of the various versions of the algorithm. The material in the paper provides a sound theoretical basis for this widely used algorithm. Such a comprehensive foundation will be useful for further research on active vibration and noise reduction in rotorcraft.

Acknowledgments

This research was supported in part by a Rackham Predoctoral Fellowship from the University of Michigan for D. Patt, and by ARO grant 02-1-0202 with Dr. G. Anderson as grant monitor. Partial support by the FXB Center for Rotary and Fixed Wing Air Vehicle Design is also gratefully acknowledged.

Appendix A. Convergence Analysis of the Estimate $\hat{T}_k$

Define $\Delta T_k$ of size $2p \times 2m$ by

$$\Delta T_k = \hat{T}_k - T,$$

where $\hat{T}_k$ is updated using Eqs. ((123))-(125)). Next, define the function $V(\Delta T, \hat{P})$ by

$$V(\Delta T, \hat{P}) = \Delta T \hat{P}^{-1} \Delta T^T$$

and $\Delta V_k$ by

$$\Delta V_k = V(\Delta T_{k+1}, \hat{P}_{k+1}) - V(\Delta T_k, \hat{P}_k),$$

where $\hat{P}_k$ is updated using Eqs. ((123))-(125)) and $\hat{P}_0$ is the positive definite matrix used to initialize Eq. ((125)). Subtracting $T$ from both sides of Eq. (124) yields

$$\Delta T_{k+1} = \Delta T_k + \epsilon_{k+1} K_{k+1},$$

while substituting Eqs. (108) and (137) into Eq. (136) yields

$$\Delta V_k = (\Delta T_k + \epsilon_{k+1} K_{k+1}) (\hat{P}_k + \Delta u_{k+1} \Delta u_{k+1}^T) (\Delta T_{k+1} + \epsilon_{k+1} K_{k+1}) - \Delta T_k \hat{P}_k^{-1} \Delta T_k^T,$$

$$= \Delta T_k \Delta u_{k+1} \Delta u_{k+1}^T \Delta T_k^T + \Delta T_{k+1} \Delta u_{k+1} \Delta u_{k+1}^T K_{k+1}^T \epsilon_{k+1} + \Delta T_k \hat{P}_k^{-1} K_{k+1}^T \epsilon_{k+1}$$

$$+ \epsilon_{k+1} K_{k+1} \Delta u_{k+1} \Delta u_{k+1}^T \Delta T_k^T + \epsilon_{k+1} K_{k+1} \Delta u_{k+1} \Delta u_{k+1}^T K_{k+1}^T \epsilon_{k+1}.$$  

Using Eq. (134), $\epsilon_{k+1}$ in Eq. (115) can be expressed as

$$\epsilon_{k+1} = -\Delta T_k \Delta u_{k+1}.$$  

Substituting Eq. (139) into Eq. (138) yields

$$\Delta V_k = \epsilon_{k+1} \left[ 1 - \frac{2 \Delta u_{k+1}^T \hat{P}_k \Delta u_{k+1}}{1 + \Delta u_{k+1}^T \hat{P}_k \Delta u_{k+1}} - \frac{2}{1 + \Delta u_{k+1}^T \hat{P}_k \Delta u_{k+1}} \right] + \frac{\Delta u_{k+1}^T \hat{P}_k \Delta u_{k+1}}{(1 + \Delta u_{k+1}^T \hat{P}_k \Delta u_{k+1})^2} + \frac{(\Delta u_{k+1}^T \hat{P}_k \Delta u_{k+1})^2}{(1 + \Delta u_{k+1}^T \hat{P}_k \Delta u_{k+1})^2} \epsilon_{k+1}^T,$$

and hence $V(\Delta T_k, \hat{P}_k)$ is non-increasing. Since $V(\Delta T_k, \hat{P}_k) \geq 0$, it follows that $\lim_{k \to \infty} V(\Delta T_k, \hat{P}_k)$ exists and is non-negative. Hence

$$\lim_{k \to \infty} -\frac{\epsilon_{k+1} \epsilon_{k+1}^T}{1 + \Delta u_{k+1}^T \hat{P}_k \Delta u_{k+1}} = \lim_{k \to \infty} \Delta V_k = 0.$$  

Next it is shown that $\Delta u_k$ is bounded. Substituting Eq. (105) into Eq. (127) yields

$$\hat{T}_k = T \Delta U_k \Delta U_k^T \hat{P}_0^{-1} + \Delta U_k \Delta U_k^T.$$  

27

American Institute of Aeronautics and Astronautics
Post-multiplying Eq. (142) by $\hat{P}_0^{-1} + \Delta U_k \Delta U_k^T$ yields

$$\Delta T_k = -T \hat{P}_0^{-1} (\hat{P}_0^{-1} + \Delta U_k \Delta U_k^T)^{-1}.$$  \hfill (143)

Note that

$$\sigma_{\text{max}}(\Delta T_k) \leq \sigma_{\text{max}}(T) \sigma_{\text{max}}((\hat{P}_0^{-1} + \Delta U_k \Delta U_k^T)^{-1}),$$ \hfill (144)

$$\leq \frac{\sigma_{\text{max}}(T)}{\sigma_{\text{min}}(\hat{P}_0) \sigma_{\text{min}}(\Delta U_{k_0} \Delta U_{k_0}^T)}.$$ \hfill (145)

If $\Delta U_{k_0} \Delta U_{k_0}^T$ is nonsingular, then, for all $k \geq k_0$, Eq. (144) implies that

$$\sigma_{\text{max}}(\Delta T_k) \leq \frac{\sigma_{\text{max}}(T)}{\sigma_{\text{min}}(\Delta U_{k_0} \Delta U_{k_0}^T)}.$$ \hfill (146)

Hence, if $\hat{P}_0$ is chosen to be sufficiently large, then $\sigma_{\text{max}}(\Delta T_k)$ can be made sufficiently small to satisfy the condition given by Eq. (40). For this case, Eq. (39) implies that, for all $k \geq k_0$,

$$\sigma_{\text{max}}(\hat{M}_k \Delta T_k) < 1.$$ \hfill (148)

The state space representation of the system dynamics with the control law, given by Eq. (128), is

$$\begin{bmatrix} z_{k+1} \\ u_{k+1} \end{bmatrix} = \hat{A}_k \begin{bmatrix} z_k \\ u_k \end{bmatrix},$$ \hfill (147)

where $\hat{A}_k$ is defined in Eq. (34) with $T$ and $M$ replaced by $\hat{T}_k$ and $\hat{M}_k$ respectively. Hence for all $k \geq k_0$

$$\begin{bmatrix} z_k \\ u_k \end{bmatrix} = \prod_{i=k_0}^{k} \hat{A}_i \begin{bmatrix} z_{k_0} \\ u_{k_0} \end{bmatrix}.$$ \hfill (151)

Note that $\prod_{i=k_0}^{k} \hat{A}_i$ can be factored as

$$\prod_{i=k_0}^{k} \hat{A}_i = \begin{bmatrix} I_{2p} & T \\ 0 & I_{2m} \end{bmatrix} \begin{bmatrix} I \\ I \end{bmatrix} \left( I + \sum_{i=k_0}^{k} (\prod_{j=0}^{i} \Delta T_j \hat{M}_{j+1}) \prod_{i=k_0}^{k} (\hat{M}_i \Delta T_i) \right) \begin{bmatrix} I_{2p} & -T \\ 0 & I_{2m} \end{bmatrix}.$$ \hfill (153)

From Eq. (146) it follows that

$$\sigma_{\text{max}} \left( \prod_{i=k_0}^{k} (\hat{M}_i \Delta T_i) \right) \leq \prod_{i=k_0}^{k} \left( \sigma_{\text{max}}(\hat{M}_i \Delta T_i) \right) < 1.$$ \hfill (156)

and from Eqs. (148)-(150), one obtains that $z_k$ and $u_k$ are bounded. Hence, for all $k = 0, 1, \ldots$, with $\gamma > 0$

$$\|u_k\| < \gamma,$$ \hfill (151)

and thus

$$\|\Delta u_k\| = \|u_{k+1} - u_k\| < 2\gamma.$$ \hfill (152)
From Eq. (108) it follows that $\hat{P}_{k+1} \leq \hat{P}_k$, which implies that

$$\hat{P}_k \leq \hat{P}_0.$$  \hspace{1cm} (153)

Hence, it follows from Eqs. (153) and (152) that

$$1 + \Delta u_k^T \hat{P}_k \Delta u_k \leq 1 + \lambda_{\text{max}}(\hat{P}_0) \Delta u_k^T \Delta u_k$$

and thus Eq. (142) implies that

$$\lim_{k \to \infty} \varepsilon_k = 0.$$  \hspace{1cm} (155)

Taking the limit as $k \to \infty$ of Eq. (124) yields

$$\lim_{k \to \infty} (\hat{T}_{k+1} - \hat{T}_k) = \lim_{k \to \infty} \frac{\varepsilon_{k+1} \Delta u_{k+1}^T \hat{P}_k}{1 + \Delta u_{k+1}^T \hat{P}_k \Delta u_{k+1}}.$$  \hspace{1cm} (156)

From Eqs. (152)-(155) it follows that,

$$\lim_{k \to \infty} \frac{\varepsilon_{k+1} \Delta u_{k+1}^T \hat{P}_k}{1 + \Delta u_{k+1}^T \hat{P}_k \Delta u_{k+1}} = 0,$$

and hence

$$\lim_{k \to \infty} (\hat{T}_{k+1} - \hat{T}_k) = 0.$$  \hspace{1cm} (158)

Thus, $\{\hat{T}_k\}$ is a Cauchy sequence, and hence $T_k$ converges. However, there is no guarantee that $T_k$ will converge to $T$. In fact, it can be shown that there are certain choices of $P_0$ and $T_0$ such that $T_k$ will not converge to $T$. For example, if $u_0 = 0$, $S = 0$, and $T_0 = 0$, then Eq. (128) implies that $u_1 = 0$. Hence, it follows from Eqs. (123) and (124) that $T_k = 0$ for all $k \geq 0$. Conditions on $T_0$ and $P_0$ that guarantee convergence of $T_k$ to $T$ are not available.
