Luck: Evolutionary and Epistemic*

Billy Dunaway
University of Oxford

Draft of 5th May, 2015

Abstract

This paper advances two theses about evolutionary debunking arguments in ethics. The first is that, while such arguments are often motivated with the rhetoric of “luck”, proponents of these arguments have not distinguished between the kinds of luck that might lead to the formation of a true belief. Once we make the needed distinctions, the relevance of the kind of luck which can be derived from broadly evolutionary explanations to the epistemological conclusions debunkers draw is suspect. The second thesis is that debunkers might successfully show that epistemic luck is relevant to their concerns. But they will need to include specific premises about the kind of evolutionary mechanism that explains the beliefs that the debunker targets. Proponents of debunking arguments, if they continue to insist on using luck-based considerations, are then hostage to empirical fortune in a way not previously recognized.

1 Preliminaries

Recently a quite large literature has emerged on the topic of evolutionary “debunking” arguments in ethics.1 Broadly, these arguments aim to show that, owing to some general features of the evolutionary origins of certain kinds of belief, those beliefs are epistemically suspect. This is just a rough schema for an argument, and within the burgeoning literature there are a variety of ways of filling out the schema. (In particular, which kinds of belief are problematic, how evolutionary origins bear on formation of the relevant beliefs, and what “epistemically suspect” amounts to are all questions any respectable version will need to answer.) One thought that often motivates the idea that some version of the argument is compelling deploys the notion of luck. It is a common theme in the debunking literature which the effects of evolutionary forces that shape our

---

1Special thanks to Matthew Benton, Julien Dutant, Daniel Fogal, John Hawthorne, Brian Hedden, Maria Lasonen-Aarnio, David Manley, Katia Vavova, Dani Rabinowitz, and audiences at University College, London and St. Andrews for many valuable comments and/or discussion of this paper.

ethical beliefs show that the beliefs in question, if true, are only so because of an accident of luck. And many epistemic notions—knowledge, justification, and the like—plausibly require the absence of a certain kind of luck. The question this paper addresses is whether the luck-based motivations for worrying about the epistemic effects of evolution are apt.

It is very natural to speak in terms of luck when considering the question of whether evolutionary forces might have produced true ethical beliefs. Street, for instance, uses such language in the following passage:

[I]t turns out that we have been evolving towards affirming whatever evaluative content tends to promote reproductive success. We have thus been guided by the wrong sort of influence from the very outset of our evaluative history, and so, more likely than not, most of our evaluative judgements have nothing to do with the truth. Of course it’s possible that as a matter of sheer chance, some large portion of our evaluative judgements ended up true, due to a happy coincidence between the realist’s independent evaluative truths and the evaluative directions in which natural selection tended to push us, but this would require a fluke of luck that’s not only extremely unlikely, in view of the huge universe of logically possible evaluative judgements and truths, but also astoundingly convenient to the realist. Barring such a coincidence, the only conclusion remaining is that many or most of our evaluative judgements are off track.²

Richard Joyce motivates a similar thought by analogy with a case that clearly involves epistemically problematic luck. This is a case where you are slipped a pill that causes belief in the claim that Napoleon lost Waterloo. It is extremely natural, given his set-up, to view your Napoleon-beliefs as only true owing to an accident of luck; one could easily have been slipped a pill which caused one to believe that Napoleon won instead. Joyce highlights the pernicious epistemic effects of such luck in the following passage:

Suppose that there were a pill that makes you believe that Napoleon won Waterloo, and another one that makes you believe that he lost […] Now imagine that you are proceeding through life happily believing that Napoleon lost Waterloo (as, indeed, you are), and then you discover that at some point in your past someone slipped you a “Napoleon lost Waterloo” belief pill. It is not a matter of your learning of the existence such pills and having no way of knowing whether

²Street (2006, 122, emphasis added). See also Street (2008, 208-9). In these and other passages Street is careful to limit the scope of her debunking argument belief in evaluative facts, construed realistically. In what follows I will assume that the argument can be extended to belief in ethical facts, and will assume that these are to be understood in a paradigmatically realist fashion. For more on whether Street’s favored version of Constructivism avoids epistemological challenges, see Dunaway (MS).
you have ever taken one; rather, we are imagining that you somehow
discover beyond any shred of doubt that your belief is the product
of such a pill. Should this undermine your faith in your belief that
Napoleon lost Waterloo? Of course it should.³

It is important to distinguish the rhetorical effect of these passages from the
official arguments Street, Joyce, and other debunkers offer. There are complicated
issues of interpretation concerning exactly which premises individual debunkers
use to support their conclusions. One possible interpretation of these arguments
is that they explicitly rely on a premise about epistemic luck. That is, some
debuffers might be arguing along the following lines:

*Argument from Luck*

Evolution influences ethical belief-formation in such-and-such way.

If evolution influences ethical belief-formation in such-and-such way, then ethical
beliefs are epistemically suspect.

Therefore, ethical beliefs are epistemically suspect.

But as debunking arguments have inspired a massive literature dealing with the
question of how best to interpret the arguments, any claim that debunkers rely on
a version of the Argument from Luck is bound to be controversial. Fortunately we
can address the relevance of luck-based considerations in debunking arguments
without taking an interpretive stand on whether any debunkers have explicitly
endorsed the Argument from Luck.

This is because luck-based considerations might play a less formal, but no
less important, role in motivating the debunker’s conclusion. When Street makes
claims about a “happy coincidence” and the effects of “sheer chance”, the vocab-
ulary bears on one natural interpretation a very close connection to luck-based
considerations. Roughly: it is very natural to hear the the claim that a belief’s
truth relies on a “happy coincidence” as claiming that, if the belief is true, then its
truth is a matter of luck. The same point goes for other proprietary terms Street
uses. And Joyce claims an “analogy” between ethical beliefs shaped by evolution
and beliefs formed by ingesting a Napoleon Pill. (He says, “The intention of this
make-believe scenario is to prime us for an analogical epistemological conclusion
regarding an evolved moral sense.”) As before, there is a natural reading on
which one central feature of the analogy is luck-based: just as the Napoleon
Pill makes one’s Napoleon-beliefs rely on an accident of luck, evolution shows
a similar reliance on luck in the case of ethical belief.

The upshot is that even if debunkers do not explicitly accept the Argument
from Luck, it is nonetheless very natural to hear their central terminology and

³Joyce (2006, 179). Similar rhetoric is found in the presentation of evolutionary arguments in
other domains in Bloom (2009, 129) and Wilkins and Griffiths (2013, 143).
analyses as relying on the epistemic consequences of luck. We can ask whether
the these intuitive force of this connection is warranted. Should we think of
beliefs that are true owing to a “happy coincidence” as epistemically suspect
because reliance on a coincidence entails the presence of epistemically problematic
luck? And should we think of ethical beliefs formed by evolution as epistemically
suspect in the same way as the Napoleon Pill beliefs, which are a clear example
of epistemic luck? Debunkers who do not rely on the Argument from Luck are
not forced into a ‘yes’ answer here. But since much of the intuitive force of their
presentation plays up the presence of luck that arises out of the evolutionary
influences on ethical belief, it is an important question whether these connections
are deserved. I will focus almost exclusively on this question, returning only
briefly to the status of debunking arguments that explicitly disavow the relevance
of epistemic luck in the concluding section.

My conclusion is a largely pessimistic one—barring some additional non-
trivial empirical premises, debunkers’ attempts to evoke problematic epistemic
luck are misplaced.

The pessimistic conclusion I will argue for consists in two theses. The first
is that evolutionary debunking arguments are quick to play up very natural
connections with luck, but systematically ignore important distinctions between
different kinds of luck. Not all types of luck in processes leading up to formation
of a true belief are epistemically problematic—in fact, some are perfectly benign.
Proponents of debunking arguments, in using the language of luck to motivate
central premises, have systematically ignored these distinctions. Absent further
premises, the evolution-induced presence of luck in ethical belief implies nothing
about the epistemic status of these beliefs.

This conclusion isn’t entirely pessimistic, however, as the second thesis is
that there may well be additional premises available to the debunker which do
establish the needed connection between evolutionary luck and the epistemic
status of ethical beliefs. In particular, if debunkers can provide additional evidence
about the specific way in which evolutionary forces have shaped our ethical
beliefs, they can rule out the possibility that the luck involved in such belief-
formation is epistemically benign. I will outline the what the specific evolutionary
processes would have to look like in order to yield this conclusion. While I will not
attempt to settle whether these processes have in fact taken the required shape,
one lesson from this second thesis is that the relevance of luck to evolutionary
debunking is hostage to empirical fortune. Not every evolutionary explanation
that proceeds broadly by a mechanism of natural selection will do the job. It
is an open (and under-explored) question, to be settled by naturalistic scientific
investigation—and not philosophical debate alone—whether luck is the right tool
for casting doubt on our ethical beliefs.

A few preliminary methodological points are in order before proceeding.
The primary focus of the following sections will be on whether a focus on luck
supports the epistemological conclusion debunking arguments. For simplicity I
will focus one epistemological notion, namely knowledge. Thus instead of asking
whether the debunker’s argument succeeds in showing that ethical beliefs are epistemically suspect, I will ask the more pointed question of whether luck is relevant to the possibility of ethical knowledge. This is not entirely in keeping with the terms used in the debunking literature, where the typical focus is not on ethical knowledge. However for present purposes this simplification is a harmless one, and the lessons from the focus on knowledge should carry over to other familiar epistemological notions as well. A central claim of this paper is that there are certain kinds of luck that are incompatible with knowledge, while others that are epistemically benign. Analogously, other epistemically significant notions will not be compatible with certain kinds of luck while tolerating other epistemically benign forms of luck.

For example some will want to think of debunking arguments as showing that ethical beliefs are unjustified, or that once one knows of the evolutionary origins for one’s ethical beliefs, one acquires a “defeater” for them. Again I will not focus on the notions of justification or defeat here, but the lessons below carry over: one way of a belief’s being unjustified is for it to rely for its truth on an objectionable kind of luck (for example the kind of luck in the Napoleon Pill case), and one way of acquiring a defeater is to learn that one’s belief, even if true, was formed in a way that relies on the relevant kind of luck. Thus proponents of justification- and defeat-based arguments will find the discussion of epistemic luck here to be of the first importance when deciding whether to invoke luck-based considerations when making their case.

One final dialectical point is in order as well. Some debunkers might insist that their argument is not to be couched in familiar epistemological terminology at all, and instead can only be stated using their own proprietary vocabulary. (One could imagine—and might even encounter in the literature—a debunker insisting that the relevant notion of ‘off-trackness’ cannot be understood by its relationship to knowledge, justification, defeat, and the like.) The versions of the debunking argument will not find the discussion of epistemic luck here to be of much interest. But such versions of the argument are also much less forceful dialectically, since most philosophers will accept that ethical belief is epistemically suspect only if it can be shown that it bears substantial and non-trivial relations to familiar epistemic notions: that it is not knowledge, is unjustified, or is susceptible to defeat. It is the relevance of luck-based considerations to these dialectically worrying versions of the debunking argument that I will focus on in what follows.

2 Knowledge and risk of error

Luck-based considerations provide some intuitive motivation for thinking that ethical belief is debunked by evolution. Does this intuitive thought survive scrutiny? Reflection on some simple cases suggests some natural parameters on when a belief is epistemically suspect due to luck. I will outline some of these parameters in the present section, but nothing in the constraints I mention here will surprising; the epistemology literature has worked over these details in more detail than I can hope to cover here. All I will do is outline enough of what I
take to be the most plausible aspects that have been noted by this literature, and
develop them in enough detail to facilitate a closer look at the relationship between
luck and evolutionary debunking.

As an entry point, consider a traditional case from Gettier (1963): Jones knows
that Smith has 10 coins in her pocket, falsely believes Smith will get the job, and
deduces that the person who will get the job has 10 coins in her pocket. As it turns
out, Jones’s belief happens to be true: Jones herself has 10 coins in her pocket, and
it is she who is the one who will get the job. But while Jones truly believes that
the person who will get the job has 10 coins in her pocket, it is natural to say that
she doesn’t know this, and one diagnosis of this is that this is because her belief
is true owing to a kind of luck.\(^4\)

Of course not just any kind of luck leading up to the formation of a true belief
is problematic in the same way. Sometimes one’s belief will owe its truth to an
accident of luck but not in a way that makes the belief fail to be knowledge. If
I happen to turn my head just in time to see that John is smiling, I can know
that John is smiling, even though I am in a sense lucky to have turned my head
and formed this belief at all.\(^5\) The Gettier case and the head-turning case involve
different kinds of luck, only one of which is relevant to knowledge. One might
use a simple “safety” condition to capture this distinction, according to which
a nearby false belief that is formed by a similar method prevents an actual true
belief from being knowledge. This is Simple Safety:

**Simple Safety** If one knows \(p\) in a world \(w\), then for any world \(w^*\) close to \(w\)
where one believes \(p\) in \(w^*\) by a similar method, \(p\) is true in \(w^*\).

Simple Safety might provide a nice first-pass gloss on why true belief in the
Gettier case isn’t knowledge (on the grounds that it could easily have been false
that Jones has 10 coins in her pocket). And it distinguishes this case from the
head-turning case (where, although one was lucky to have turned one’s head, in
the nearby worlds where one hasn’t, one forms a false belief by a very dissimilar
method.) However we need to refine Simple Safety in a number of ways. For
instance it cannot deliver the same verdict in similar cases where the belief in
question is a belief in a necessarily true proposition, since these propositions are
guaranteed to be true in all close worlds. (This problem is especially relevant in
when evolutionary debunking of “basic” ethical beliefs is at issue in the following
sections, as the contents of these beliefs are plausible candidates for propositions
that are necessarily true if true at all.) Also the appeal to beliefs that are formed
by the “same” method will prove unsatisfactory in cases where issues of method-
individuation arise. Here is a revision of Simple Safety that avoids some of these
difficulties:

\(^4\)Dancy (1985, 134)
\(^5\)See similar examples in Pritchard (2004, 133 ff.); see also Kahane (2011, 105-6) for a preliminary
discussion of kinds of luck as they pertain to debunking arguments.
If one knows \( p \) in a world \( w \), then for any world \( w^\ast \) close to \( w \) where in \( w^\ast \) one believes a proposition \( p^\ast \) similar to \( p \), and the token causal process which produces the belief in \( p^\ast \) in \( w^\ast \) is similar to the token causal process which produces the belief in \( p \) in \( w \), the belief in \( p^\ast \) in \( w^\ast \) is true in \( w^\ast \).  

According to Safety, true beliefs in necessary propositions can fail to be knowledge. This is because of the requirement that similar beliefs in close worlds be true. If I correctly guess that 154 is the sum of 81 and 73, I still won’t count as knowing that 154 is the sum: given that I was guessing, I could easily have guessed a different number and believed (say) that 183 is the sum.

Not everyone will be happy with the luck-based approach to these cases, and will reject Safety and any natural refinement to deal with recalcitrant cases. Fortunately for the purposes of the present paper we needn’t settle these high-level epistemological disputes. For if luck-based considerations are irrelevant to simple cases where one knows (or fails to know) an ordinary proposition, then the rhetoric that associates ethical belief with luck-related issues owing to its evolutionary origins will be a non-starter. If luck has nothing to do with absence of knowledge in simple cases, then the debunker will be doing herself no favors by motivating a debunking of ethical belief with ties to luck. She will need to find some other motivation for the argument which clearly eschews associations with problematic epistemic luck. Against this background, it is safe to take an assumption of Safety, or a similar principle that delivers the same verdict for core cases, as common ground.

As these examples suggest, the causal history of a belief can in principle show that the belief is lucky in a way that is incompatible with knowledge. But not every instance of luck in a causal history implies a failure of Safety; only similar beliefs in nearby worlds that are formed by similar token processes need to be true. This makes the details of a causal history highly relevant to the relevant belief’s epistemic status.

Before applying these lessons to causal histories that include evolutionary processes we can, as a warm-up, consider two simple cases. In these cases the risk of error is the same, but they differ in where the risk is situated in the causal history. Varying cases in only this way makes changes the epistemic status of the beliefs which are the result of the causal process.

The first case is Coin in the Head, adapted from a case in White (2010, 599):

**Coin in the Head:** You are forming beliefs about your immediate environment. Inside your head, the various neural pathways involved

---

6Compare Sosa (1999, 142), Williamson (2000, 325), Pritchard (2004, 163), and Hawthorne (2004, 55-6). One might wish to modify Safety to account for cases where one’s belief-forming process fails to produce any belief at all (perhaps owing to reference failure—see Manley (2007)). I will omit these complications from the main discussion.

7Terminological note: here and in what follows, I will speak of beliefs satisfying of failing to satisfy Safety. By this, I mean that they do not satisfy the consequent of the conditional labeled Safety, and hence on present assumptions do not constitute knowledge.
in your belief-forming process all lead to a box. In the box is a coin that
gets flipped around. The outcome of the coin flipping is objectively
random, and as it flips your beliefs change in a systematic way: when
the coin lands ‘heads’, you form the beliefs that you are located on
Earth, and that you are a human with a body. These beliefs are, how-
ever, “hardwired” into your brain; all that is needed to produce them is
your specific cognitive architecture and the coin’s being heads side up.
When the coin lands ‘tails’, your brain is hardwired to form different
beliefs: you form the false beliefs that you are located on Mars, and
that you are merely a brain with quasi-perceptual experiences caused
by electrode stimulation. As the coin is flipped, you lose memory
of your previous beliefs and cannot notice any inconsistency between
your quasi-perceptual beliefs over time.

Very plausibly, one can’t know that one is on Earth in Coin in the Head. Safety
provides a natural and plausible explanation for why this is so, even when the
coin is on ‘heads’ and your beliefs are mostly true. Worlds where the coin is on
‘tails’ are very close—if an objectively random coin flip had turned out differently,
you would have been in one of these worlds. And if one were in such a world,
one’s beliefs in either outcome are quasi-perceptual, and are sufficiently similar
beliefs. They are formed by a similar processes, as in both outcomes one’s beliefs
are the product of the coin flip plus hardwiring. And in the ‘tails’ world one’s
beliefs are false.

By varying the causal history of your belief without eliminating the need for
luck in arriving at a true belief, we arrive at a very different epistemological
verdict. Consider a related case, which we can call God’s Coin:

God’s Coin: God created you five minutes ago, and before doing so,
God flipped a coin. If the coin landed ‘heads’, God would create you in
the environment you are actually in, and moreover would give you a
normal human visual system and cognitive architecture that produces
the true beliefs that you are located on Earth and are a human with
a body. If the coin landed ‘tails’, God would not have given you
a perceptual system, but rather would have given you credible but
misleading testimony, on the basis of which you would form the false
beliefs that you are located on Mars and are merely a brain with quasi-
perceptual experiences caused by electrode stimulation. The outcome
of God’s coin flip is objectively random.

Suppose again the coin landed ‘heads’. Unlike Coin in the Head, it is quite plau-
sible to say that one knows propositions about one’s condition and environment.
(After all, one can clearly see that one is on Earth in this case.) But intuitively worlds
where one has false beliefs about being an envatted brain on Mars are just as close
in God’s Coin as they are in Coin in the Head: the outcome of the coin flips are
objectively random in both cases, and the coin could easily have landed ‘tails’ in
each. And in each ‘tails’ scenario, you by and large have the same false beliefs. The crucial difference is these beliefs are plausibly produced by sufficiently dissimilar processes in God’s COIN. While the false beliefs are produced by a ‘tails’ outcome are the products of believing on the basis of testimony, the true beliefs in a ‘heads’ outcome are the products of a human visual system interacting with its environment. Since beliefs produced by similar perceptual processes are true in all nearby worlds, one’s true beliefs in the ‘heads’ outcome satisfy Safety.

Comparison of God’s COIN and Coin in the Head serves to illustrate the importance of similarity of belief-forming processes to Safety. But more generally, it points to the way in which Safety captures a very natural and important distinction between different kinds of luck in true belief. Some but not all kinds of luck are incompatible with knowledge. Let us reserve the term epistemic luck for the kind of luck that begets a failure of Safety. Epistemic luck is the kind of luck that is present in Coin in the Head. But there are other kinds of non-epistemic luck that might lead to formation of a true belief, and these kinds of luck are not incompatible with knowledge. For instance, whatever luck is required for a true belief in God’s COIN, is not epistemically problematic luck.

We need, then, to keep the distinction between epistemic luck and other kinds of luck in mind when assessing whether a the need for luck of some kind in the causal history of a belief implies that it is epistemically suspect. In the next section, I outline the case that appeals to luck in evolutionary debunking arguments have run afoul of these distinctions.

3 Evolutionary luck

3.1 The appeal to luck in general form

We outlined in §1 the intuitive connection between evolutionary debunking and luck. It is easy to see why luck of some kind or other would be necessary for true ethical belief: it is plausible (and I will assume here) that the evolutionary forces that shape these beliefs are not themselves concerned with producing true beliefs. While evolution might select for creatures who are disposed to form certain ethical beliefs, it is no part of the evolutionary process that these beliefs are selected for because they are true. If one forms the beliefs evolution selects for, and thereby forms true beliefs, it is no stretch of ordinary language to say that one is thereby lucky in some sense.

But this does not get us very far by itself. We concluded the previous section by noting that not every instance of luck in forming a true belief is epistemically relevant, so we should be careful about what kind of luck is present owing to the evolutionary origins of the relevant beliefs. One might be lucky in some sense but still have knowledge, as in God’s COIN. The present section carries out this neglected task, and looks at whether evolutionary origins make it at all plausible that ethical beliefs are dependent on epistemic luck.

First, more detail is needed about the contours of the evolutionary origins that feature in the debunker’s argument. Debunkers do not typically claim that any
belief that has an evolutionary explanation is epistemically suspect. Instead they only wish to target beliefs with a certain kind of evolutionary explanation. To get an initial grasp of the kind of explanation that debunkers have in mind, a contrast case might be helpful.

Consider an evolutionary explanation of perceptual beliefs. A system for forming beliefs about one’s immediate environment will plausibly confer a selection advantage on an organism only if it produces true beliefs about the organism’s environment. Perceptual beliefs are causal inputs into processes that are directly related to survival and reproduction, such as finding food and avoiding predators. And perceptual inputs about the immediate environment will be better suited to producing these behaviors that confer selection advantages if they are true. So it is no evolutionary accident if one finds oneself with a true belief-producing perceptual system: natural selection will favor perceptual systems that generally produce true beliefs about the environment rather than false beliefs.

Arguably analogous claims cannot be made for ethical beliefs. For one illustration of this idea we can take the outline of the evolutionary explanation of why we form ethical beliefs that Joyce (2006) favors: roughly, ethical belief provides a selection advantage because organisms who have the capacity for ethical belief will do better at resisting the temptation to cheat to obtain short-term goals when such cheating is disadvantageous in the long term. According to this proposal, (i) there is a selection advantage being resistant to short-term temptations, and (ii) one way of acquiring this advantage is to acquire the capacity to form ethical beliefs. The crucial feature of this story for our purposes is that this selection advantage is available regardless of whether it is true that one ought to avoid succumbing to temptation. (Other evolutionary explanations will have a similar upshot; I focus on Joyce’s solely for the purposes of illustration.)

In this respect there is an important contrast with perceptual belief. If our ethical beliefs are true, it is not because of natural selection favored an ethical belief-forming module that produces true ethical beliefs. Debunkers have found talk of accidents and luck to be appropriate in light of this difference, and this

---

8See Vavova (forthcoming) for more on the details of the debunker’s evolutionary premise. Here I will focus on the aspects of evolutionary processes that might plausibly be thought to have consequences relevant to the question of epistemic luck.

9Wilkins and Griffiths (2013, 139)

10Here is Joyce:

[A] person who in addition to being sympathetic judges that cheating is morally wrong will feel very differently if on occasion she succumbs to temptation. She can tell herself that she has done something wrong, that her action was unfair or unjust, that she must make amends, that she not only has risked punishment but deserves it. The emotion of guilt is available to her […] The fact that these more robust forms of self-recrimination are available to the moralized thinker when she does cheat strongly suggests that when she is behaving herself her motivation not to cheat is more reliable and resolute than that of her non-moralized counterpart. (Joyce, 2006, 112-3)

It should be noted that this idea is not wholly uncontroversial: one can read Enoch (2011, 168 ff.) as challenging the claim that every evolutionary explanation for ethical belief will not imply that, or even raise the probability that, those beliefs are true.
is the feature of ethical belief that makes the motivations from luck sketched in §1 seem especially plausible. We can grant that the debunker is on to something; there is plausibly some difference between ethical and perceptual belief-forming mechanisms in this respect. We can even use ‘luck’ to label the feature that the debunker has latched on to. In order to not prejudge matters, let us call it evolutionary luck. Ethical beliefs require evolutionary luck in order to be true, while perceptual beliefs do not.

By calling this a species of luck, we haven’t thereby shown anything about the epistemic status of these beliefs. Evolutionary luck isn’t necessarily a species of epistemic luck. Rather, accusations of a need for luck will be relevant to a successful debunking argument only if an additional premise connecting the presence of evolutionary luck with epistemic luck holds. This is Luck Connection:

**Luck Connection** If a belief requires evolutionary luck, then it requires epistemic luck.\(^{11}\)

If Luck Connection is true, then the epistemic consequences that attend to epistemic luck, including its incompatibility with knowledge, are available to the proponent of the debunking argument. Allegations of an objectionable reliance on luck in ethical belief will be entirely apt. In particular, the debunker can claim that since it is a consequence of evolution theory that ethical beliefs are subject to evolutionary luck, it follows from Luck Connection that these beliefs are subject to epistemic luck.

In the remainder of this section, I will consider two ways of arguing that Luck Connection is true.

### 3.2 Conceptual possibilities

At a structural level, epistemic luck can be present in two ways. The first way arises when a belief isn’t sufficiently sensitive to the fact it is about. If a true belief is lucky in this way, there are nearby worlds where one has the belief but the facts it is about have changed, and so the belief is false in nearby worlds. One is lucky to not have been in the nearby world with a false belief.

Does the phenomenon of evolutionary luck in ethical belief give rise to epistemic luck? To make use of the first structural feature of epistemic luck, one needs to show that ethical belief which fails to be sufficiently sensitive; this involves showing that one retains one’s beliefs in worlds where the ethical facts are different. As a textual note, there are some passages in Street’s writings which suggest that she has a picture like this in mind when she alleges that ethical beliefs require objectionable luck:

\(^{11}\)Terminological note: I will use phrases like ‘belief \( b \) requires evolutionary luck’ as shorthand for ‘if \( b \) is true, then \( b \)’s truth is a matter of evolutionary luck’. Similarly for the phrase ‘\( b \) requires epistemic luck’.
[A]s a matter of sheer luck, evolutionary pressures affected our evaluative attitudes in such a way that they just happened to land on or near the true normative views among all the conceptually possible ones.  

One feature of this passage deserves special attention. Suppose one’s basic ethical beliefs are true. What are worlds like where one has those same basic ethical beliefs and thereby has a false belief? These are worlds where the basic ethical facts are different. But, quite plausibly, the basic normative facts—whatever they turn out to be—are necessary. So, there are no metaphysically possible worlds where one has the same ethical beliefs and yet they are false. Such worlds are nonetheless conceptually possible—and this is a point Street explicitly acknowledges in the passage quoted above, which conspicuously avoids the claim that there are metaphysical possibilities where a different ethical system is true.

One can use these possibilities (viz., counter-possible possibilities where ethical beliefs are held fixed and the basic ethical facts they are about are different) to forge a connection between evolutionary and epistemic luck, and thereby show that Luck Connection is true. First, if a belief requires evolutionary luck, then in the possibilities where the basic ethical facts are different, evolution will not change course and produce correspondingly different ethical beliefs. The same beliefs confer survival advantages as in the actual world; this fact is not sensitive to the change in ethical facts, and so in worlds where the basic ethical facts are different but evolution operates in the same way, one will have false beliefs. This is a general consequence of the nature of evolutionary luck:

1. If a belief requires evolutionary luck, then in worlds where that belief is produced by a similar (evolutionary) process but the facts are different, one has false beliefs.

This observation only lends support to Luck Connection in conjunction with the following premise:

2. If in worlds where a belief is produced by a similar (evolutionary) process but the facts are different, one has false beliefs, then that belief requires epistemic luck.

1 and 2 together guarantee that if ethical belief requires evolutionary luck, then it also requires epistemic luck. Given that it is also plausible to grant the debunker that ethical belief does require evolutionary luck, we have the makings of an argument for Luck Connection.

The problem for this argument is that 2 is false given some very natural assumptions. First, recall that the worlds which satisfy the antecedent of 2 are worlds that are metaphysically impossible: they are worlds where the basic ethical facts are different, while the processes which ethical beliefs remain the same.

---

12Street (2008, 208-9). See also Clarke-Doane (2012, 334 ff.) for more discussion of attempts to turn this insight into a canonical version of the debunking argument.
Second, recall what epistemic luck requires: that there be a nearby world where one has a similar but false belief. But third, it is very plausible that metaphysically impossible worlds are not nearby worlds—that is, they are not worlds we could easily have been in; we are not at present at risk of being in such a world. There are some difficult questions for anyone who wants to understand fully what it takes to be a “nearby” in the sense relevant to epistemic luck. But cases involving metaphysically impossible worlds are not among the difficult cases.13

There is more to be said about 2 for the debunker, although it is questionable whether this helps her case that there is a significant role for epistemic luck to play in debunking arguments. Rather, the point might best be construed as a possible diagnosis of why the debunker has been misled into thinking that Luck Connection is true. Begin with the observation that, according to Safety, the distant possibilities where one’s ethical beliefs are false (owing to a counter-possible change in the ethical facts) are not irrelevant to what one can know. This is because of the following: while knowing \( p \) requires that the belief that \( p \) is safe; knowing that one knows \( p \) requires safely believing that one knows \( p \). Knowing that one knows \( p \), in other words, requires that the belief in \( p \) be safely safe: not only could a belief similar to belief that \( p \) not easily have been false, but in addition the belief that belief in \( p \) is safe itself could not easily have been false.

These do not come to the same thing.14 One can know \( p \), which means that one’s belief in \( p \) is safe, and yet not know that one knows \( p \), since one’s belief that belief in \( p \) is safe isn’t safe. Unpacking a bit: suppose that, in any nearby world, beliefs similar to the belief that \( p \) are true. One’s belief is safe, and can be known. But to know that one knows \( p \), one’s belief that one knows \( p \) must be safe. Even if it is true that one’s belief in \( p \) is true in nearby worlds, it might be that in some of these nearby worlds, one’s belief that one knows \( p \) is false. This happens if, in a world that is nearby to a nearby world, one’s belief in \( p \) is false. Worlds that are near to nearby worlds aren’t ispo facto nearby themselves. And false beliefs in worlds that are near to nearby worlds preclude knowledge that one knows \( p \), without precluding knowledge of \( p \).

The point generalizes to further iterations of knowledge. A false belief in a worlds nearby to a nearby to a nearby world precludes knowing that one knows that one knows, though not necessary shorter iterations of knowledge. And so on.

The debunker has pointed out that there are guaranteed to be counter-possible worlds where one has false moral beliefs. These are not guaranteed to be nearby worlds, I have pointed out, and so these counter-possible worlds do not show that one’s ethical beliefs are lucky. But their being counter-possible is no barrier to their being some iteration of nearbyness to nearby worlds. So one might argue that the debunker’s counter-possible worlds are guaranteed to show that some iteration of knowledge is unavailable because the belief that one has one fewer iterations of knowledge will, while true, be objectionably lucky. One will not be

---

13See Clark and Rabinowitz (2011) for a related point in the case of religious belief.
14More rigorous discussion of this point can be found in Williamson (2000) and Williamson (2011). I will stick with informal glosses of the issue here.
able to know that one knows ethical facts, or will not be able to know that one knows that one knows, or . . . .

Debunkers, however, are naturally interpreted as claiming that the epistemic import of evolutionary luck is stronger than this: they not only take the presence of evolutionary luck to show that some iteration of knowledge of ethical claims is unavailable; they take it to show that no knowledge is available. Counter-possible where the basic ethical facts are different need to get us from 1 to the claim that the first-order ethical beliefs are epistemically lucky. We could get this result if we collapse iterations of nearbiness: that is, if any world that is nearby to a nearby world is a nearby world simpliciter. But this is a drastic measure. It threatens to allow any possibility where one’s belief is false to count as nearby, and hence show that even if one succeeds in forming a true belief, there is a nearby possibility where one believes falsely. Epistemic luck under such an assumption threatens almost any ordinary belief, since there is some possibility of believing falsely on any matter. Debunkers would do well not to rely on such an assumption when claiming that epistemic luck infects ethical belief.

3.3 Belief-similarity

There is a second way in which epistemic luck can manifest itself. Even if the facts targeted by a belief are fairly stable—that is, if the facts are the same across all nearby worlds—one’s belief-forming methods might not produce beliefs in a way that matches the factual stability. Epistemic luck in Coin in the Head arises in this way. So there is another way in which ethical beliefs might require epistemic luck, and this does not rely on the relevance of counter-possible conceptual possibilities where the basic ethical facts are different.

To show that ethical beliefs are epistemically lucky in this way, one needs to show that there are nearby worlds where one has similar but false beliefs. This can arise not because the basic ethical facts have changed in these worlds, but rather because ethical beliefs in these worlds fail to accurately represent these facts. This is what happens in Coin in the Head: owing to the coin-flipping hardwiring, one’s quasi-perceptual beliefs about the outside world are different (and false) in nearby worlds where the coin lands ‘tails’. Nearby changes in one’s outside environment (if there are any) are not the source of epistemic luck in this case.

So the question arises: if ethical beliefs require evolutionary luck, is this enough to show that they also require epistemic luck, owing to the nearby possibility of different but false basic ethical beliefs? Evolution might be thought to be working like the box in cases where beliefs are subject to evolutionary luck: if natural selection doesn’t favor ethical beliefs because they are true, then it might have produced different beliefs that have the same survival value but a different truth-value. One might think that for similar reasons evolutionary luck gives rise to epistemic luck. This would establish Luck Connection.

---

15 This would validate the claim Williamson (2000) labels ‘KK’ and provides compelling counterexamples against.
There are two premises in this argument. The first is an alleged consequence of evolutionary luck:

3. If a belief requires evolutionary luck, then evolution could have easily have produced a similar but false belief;

The second draws a connection between this consequence and epistemic luck:

4. If a belief is such that evolution could have easily have produced a similar but false belief, then that belief requires epistemic luck.

I have briefly sketched reasons why we might accept 3: roughly, because evolutionary luck by definition implies that a belief was not selected for because it is true. There are a number of questions that remain about 3, but suppose we grant it. Still, 4 is false. The reason is that, with a appropriately nuanced understanding of epistemic luck in hand, its presence does not follow from the nearby possibility of a similar but false belief alone. The nearby false belief needs, in addition, to be the product of a sufficiently similar causal process. Otherwise it is like my belief that John is smiling, formed as I happened to turn my head just as he began to smile. I might easily have had a false belief since I could easily have not turned my head and believed that he is not smiling on the basis of what I know about John’s current mood. But the nearbyness of this scenario is not a threat to knowledge, since the false belief is formed by a very different process. There is luck in this situation, but it is God’s Coin-type luck, and is not epistemically problematic.

This isn’t a mere technical quibble, and is instead very important for a discussion of the import of evolutionary luck. For purposes of illustration, consider a simple version of a plausible evolutionary explanation for another type of belief which plausibly also requires evolutionary luck: belief in supernatural entities. One hypothesis which implies the need for evolutionary luck in supernatural belief is the following (some but not necessarily all hypotheses will have similar consequences, I discuss one hypothesis here for the sake of concreteness). Belief in non-embodied supernatural entities is a product of a “hyper-active agency detector”, or a “HAAD” for short. A HAAD is a cognitive mechanism that is prone to attribute changes in one’s environment to agents, rather than non-agential forces. The selection advantage of a HAAD is of the “better safe than sorry” variety: believing that the rustling in nearby bushes is caused by a predator or enemy, rather than the wind, will cause you to take evasive measures. While there is a cost to engaging in such behavior and being wrong about the presence of a malicious agent, there is a much higher cost to not forming the belief about a nearby predator, taking no evasive measures, and being wrong. So a HAAD will confer a survival advantage.

Such a system will overgenerate. Even when a belief in the presence of an agent doesn’t directly increase chances of survival, creatures with a HAAD will be disposed to find agents in all kinds of situations. This is part of the causal process that produces belief in the supernatural: an agent with a HAAD will find gods in
cloud formations, spirits in unexplained occurrences in their surroundings, and so on.\textsuperscript{16} Thus the HAAD hypothesis is one on which supernatural belief requires evolutionary luck, in our sense: a HAAD would have survival value whether or not the supernatural beliefs it produces are true.

Evolution isn’t guaranteed to produce agents with a HAAD, even if it in fact did. Agents without a HAAD could have been selected for given the right environment or appropriate chance events, and these agents might have formed different beliefs in the supernatural, or denied its existence altogether. But even if this is so, it does not follow from the HAAD-hypothesis that beliefs in the supernatural are epistemically lucky. Evolution, we have granted, could have easily have produced a similar but false beliefs. But these beliefs will be produced by a very dissimilar process—in worlds where evolutionary processes explain rejection of the supernatural, nothing like a HAAD will be involved in the token causal processes leading to the production of these beliefs. So \textit{4} is false for beliefs in the supernatural produced by a HAAD.

Return now to empirical hypotheses about the evolutionary origins of ethical belief. They might be like the HAAD-hypothesis for belief in the supernatural, for epistemic purposes, and evolutionary outcomes where false ethical beliefs are formed are outcomes where very different mechanisms are selected for. But it is not a certainty, prior to empirical investigation, that every available hypotheses will be the same consequence, where in nearby worlds where one forms a different but false belief, that belief is the product of a very dissimilar process. This is a question I return to in §4. For now, we can settle for an intermediate conclusion: that the HAAD hypothesis shows that evolutionary luck does not guarantee epistemic luck. Even if evolutionary luck implies the possibility of nearby error, it does not guarantee that these nearby errors will be of the kind that give rise to threatening epistemic luck.

To sum up: evolutionary origins of ethical belief do not, by themselves, do much to show that epistemic luck infects ethical belief. Debunkers have been quick to throw around allegations of luck for evolutionarily-explained ethical beliefs. But they have not distinguished between kids of luck that are epistemically problematic, and those that are not. Their allegations of luck are much less compelling when these distinctions are kept clearly in mind.

4 When do epistemic and evolutionary luck coincide?: the way forward

While there is a risk that debunkers conflate the category of epistemic luck with other epistemically benign forms of luck, we haven’t shown here that the categories of evolutionary and epistemic luck never overlap. Debunkers might favor a less ambitious claim and try to show that, even if evolutionary luck does not by itself guarantee that ethical beliefs require objectionable epistemic luck, there are other, additional features of the evolutionary explanation for ethical belief that can be brought to bear in securing this conclusion. The prospects for luck to assist the debunker’s argument are then not closed, but will have to pay

\textsuperscript{16} Bloom (2009)
special attention to whether it is empirically plausible that the best evolutionary explanations for ethical belief have the needed features. I will close by outlining some constraints on a project of this kind.

4.1 Belief-forming processes

The problem for the second route to establishing Luck Connection is that, for some evolutionary explanations for a belief, the only way for a different belief (and hence a belief with a different truth-value) to arise is for evolution to select for a distinct cognitive mechanism. That is, for some theories, instances of Mechanism Correlation hold where $b$ is a basic ethical belief:

**Mechanism Correlation** If the belief $b$ is produced by the cognitive mechanism $M$, then in any nearby possibilities where one forms the false belief $b^*$ instead of $b$, $b^*$ is produced by the distinct cognitive mechanism $M^*$.

If Mechanism Correlation holds, then it is highly plausible that the nearby possibility for forming the false belief $b^*$ does not threaten $b$ with problematic epistemic luck: for the token processes which lead up to the beliefs will go via two distinct cognitive mechanisms and, as a result, will not be very similar. Threats of epistemic luck will not be very credible for empirical theories that accept it.

Of course not every way of working out an evolutionary theory of ethical belief implies Mechanism Correlation. Instead it is empirically possible that the best working out of such a theory posits a single mechanism which is capable of producing both truth and false ethical beliefs. On such a theory, evolution would have selected for ethical belief-forming mechanism that structurally resembles the box in Coin in the Head. The same mechanism produces both true and false beliefs in nearby worlds, and hence instances of Process Similarity, where $b$ is a basic ethical belief, are true on such a theory:

**Process Similarity** For belief $b$, there are similar but false beliefs $b^*$ in nearby worlds, where the token process which produces $b$ and the token process which produces $b^*$ are very similar.

Theories which imply that ethical beliefs are subject to epistemic luck must be consistent with Process Similarity for ethical beliefs.\(^{17}\)

\(^{17}\)In order to be consistent with Process Similarity, a theory must entail the denial of Mechanism Correlation. But note that the denial of Mechanism Correlation does not, by itself, entail Process Similarity. Presumably all human visual systems have the same evolutionary explanation, but it is false that any two token beliefs in the proposition that *War and Peace* is a long book formed by perception are produces of relevantly similar causal processes. You might believe this by looking at the table of contents and noticing the page count, and your friend might believe it by looking at the closed book from the side and noticing that it is thick. Suppose both processes are ones that you might have instantiated (you and your friend are in the same room) and you could easily have formed a false belief by looking at the table of contents (since the printer was highly unreliable). If you actually look at the book from the side, it doesn’t follow that you could easily have had a false belief by a similar process because you could easily have looked at the table of contents instead. And this is so even though you would be using your visual system in either case. The token causal visual processes producing the belief that *War and Peace* is long are not sufficiently similar.
This provides a template for the claims the debunker needs in order to successfully vindicate allegations of epistemic luck. A plausible case that the template is satisfied will be largely empirical in nature. To illustrate: the HAAD hypothesis from §3 as an explanation of belief in the supernatural is an empirical claim that goes beyond the simple assertion that evolution somehow conferred a propensity to form beliefs in the supernatural. It is a hypothesis about the psychological mechanisms in which this propensity is realized. It is consistent with MECHANISM CORRELATION and is inconsistent with PROCESS SIMILARITY. But other psychological hypotheses about the same phenomena will yield different results. Suppose that the correct explanation for a propensity to form religious beliefs is not the HAAD-theory, but is instead that religious belief is the product of wishful thinking. Leaving the empirical plausibility of the wishful thinking theory to the side, the theory plausibly which entails that religious belief, even if true, is epistemically lucky. Even if wishful thinking produces true religious beliefs in a subject, similar but false beliefs could easily have been formed by a similar process of wishful thinking. One could easily have wanted different things (one could want for instance that atheism rather than theism to be true), and in this case one would have formed similar by false beliefs by similar processes.18

So which theory of the cognitive mechanism that leads to the formation supernatural beliefs is true matters a great deal when we are assessing whether such beliefs require epistemic luck. If the wishful thinking theory is true, PROCESS SIMILARITY is true for religious belief, and a good case for epistemic luck can be made. But if the HAAD theory is true, the prospects for the epistemic luck criticism are significantly worse. Arguments over epistemic luck for ethical beliefs will follow the same contours. Some evolutionary theories will not rule out METHOD CORRELATION, and will not provide a suitable basis for criticisms from epistemic luck. On the other hand theories which imply PROCESS SIMILARITY will be more promising. Whether the debunker has the tools needed to properly raise the issue of epistemic luck is, in large part, and empirical question.

4.2 Propensities and environmental luck

In closing I will outline one further aspect of the template that needs to be filled out in order for epistemic luck to be relevant to the debunker’s purpose. Again it will be an empirical question whether this aspect of the template is satisfied.

It is unlikely that evolution properly explains ethical belief; an empirically plausible evolutionary theory will, at best, explain a widespread propensity to form these beliefs. Propensities constitute only a partial explanation for why a particular individual has a particular belief. To illustrate: suppose a HAAD-like

18See for example Nagel (1997, 130):

I want atheism to be true and am made uneasy by the fact that some of the most intelligent and well-informed people I know are religious believers. It isn’t just that I don’t believe in God and, naturally, hope that I’m right in my belief. It’s that I hope there is no God! I don’t want there to be a God; I don’t want the universe to be like that.
faculty is responsible for a propensity to form beliefs in the supernatural. One wouldn’t want to say that the presence of a HAAD guarantees that an agent will have such beliefs; plenty of atheists exist, and presumably their cognitive architectures still include a HAAD. It simply confers an unactualised propensity to form beliefs in the supernatural.

That it is propensities which are the products of evolutionary explanation is doubly relevant to questions of epistemic luck. First, it makes the claim that one could easily have formed similar but false beliefs easier to establish. But, second, it also makes the claim that the false beliefs would have been formed by a similar process more difficult to establish. I take each of these in turn.

First: as an initial approximation, take the relevant propensities to be dispositions that manifest themselves in some but not necessarily all environments. A propensity to form certain ethical beliefs, then, is a disposition to form such beliefs in certain environments. Moreover, this disposition need not manifest itself by producing the same ethical beliefs across a range of different environments. Suppose Joyce’s explanation of ethical belief, on which it confers a selection advantage by enabling organisms to resist the temptation to cheat for short-term gains, is correct. The disposition that confers the relevant selection advantage produces different specific ethical beliefs in different environments: one might have this disposition and form utilitarian ethical beliefs in one environment, but might in a different environment have this same disposition and yet believe a rights-based morality. Which specific set of beliefs a token individual ends up with is explained not just by this disposition, but by its interaction with the rest of the individual’s cognitive faculties, their cultural setting, and other environmental factors.

If the disposition to form ethical beliefs might have produced different beliefs in different environments, one might naturally reason as follows: one could easily have been in a different environment, and if one were in that environment, one’s disposition to form ethical beliefs would have manifested itself by leading to the formation of possibly false ethical beliefs. Taking propensities seriously appears to make one component of epistemic luck easier to establish, since one will be able to find environments where the agents in question have similar but false beliefs.

Now for the second point: the focus on propensities makes another aspect of epistemic luck, which requires Process Similarity, more difficult to establish. Let D be the disposition to form ethical beliefs which evolution has selected for. And let $E_1$ and $E_2$ be different environments broadly construed in which D might be placed, where D produces the belief $b_1$ in $E_1$ and the belief $b_2$ in $E_2$. And finally, let us suppose that the beliefs $b_1$ and $b_2$ cannot both be true in their respective environments. The question pertinent to epistemic luck is whether the token causal process which involves D in the environment $E_1$ and produces $b_1$ is sufficiently similar to the token process which involves D in $E_2$ and produces $b_2$. Even if the dispositions in the two cases are the same, it is still a further question
whether the entire token causal processes leading up to the beliefs in the two cases are sufficiently similar.\textsuperscript{19}

If evolution is going to have implications for the presence of epistemic luck, the answer to be ‘yes’.\textsuperscript{20} This is a question, however, which cannot be answered in the abstract. Different answers to this question may well be plausible depending on what exactly the disposition \( D \) is, and how the relevant environments interact with the disposition to produce beliefs. Some dispositions evolution selects for might be realised in very robust cognitive mechanisms where it is quite natural to think that any two beliefs that are products of such a mechanisms are formed by similar token processes, even if strictly speaking other inputs to the mechanism are needed for it to produce any beliefs. But there is no guarantee that evolution selects for a disposition that is realised in this way; other hypotheses may deliver different results. Again, crucial questions about the role of epistemic luck in debunking arguments are such that their answers depend on the results of evolutionary biology and cognitive science.

5 Conclusions

Debunkers have been quick to raise considerations of epistemic luck when motivating their case that there is something epistemically defective about ethical belief owing to its evolutionary origins. But serious reflection on the nature of epistemic luck, and what distinguishes it from benign cases of luck, suggests that the connection between evolution and epistemic luck is tenuous. Those that wish to continue to press a link between evolution and epistemic luck will need to marshal specific (and no doubt controversial) evolutionary explanations of ethical belief which fit the template outlined in §3.

This does not mean that evolutionary debunking arguments can be safely ignored. Debunkers might defend the needed empirical hypotheses that fit aspects of the template outlined in §3. Alternatively they might retract their suggestions that epistemic luck is relevant to the epistemological upshot of evolutionary debunking arguments. There may be something left to these arguments, once the allegations of luck are scaled back.

Nothing I have said here rules out this latter strategy. But it will be worth pointing out how the debate over debunking arguments can be expected to play out, and what obstacles the debunker can expect to face, given such a move. First, the supposed analogies with non-evolutionary cases where epistemic luck explains an intuitive verdict will need to be discarded. It is worth revisiting Joyce’s Napoleon Pill case in this connection: since the presence of epistemic luck explains why one’s Napoleon belief is epistemically suspect, it will no longer serve as a motivating analogy for the debunker’s thought that ethical beliefs explained

\textsuperscript{19}For more on these issues, see Dunaway and Hawthorne (Forthcoming).

\textsuperscript{20}Obviously the prospects are better here than they are in §2.3: in the present case, we have at least guaranteed that the disposition \( D \) is a part of the token belief-forming process in both cases, so some similarity is guaranteed. When evaluating premise 4, we could not even assume this much: the presence of evolutionary luck in a belief guarantees that very little will be held in common between the process producing a true belief and a nearby process producing a similar false belief.
by evolutionary forces are similarly suspect. We know that the epistemically
important features of the Napoleon case are not present in the evolutionary case,
and so any intuitive support for the debunker’s verdict from the analogy goes
missing. Similar points apply to use of terminology like “coincidence”, “accident”,
and the like. When we understand the debunker’s use of these terms, we need
to keep in mind that, if the debunker warranted in using them, they cannot entail
that the beliefs in question require epistemic luck.

Second, once these misleading suggestions are discarded, the debunker will
need to find another route to motivating the thought that there is anything
epistemically worrisome in evolutionary luck. It isn’t obvious that there is
anything problematic here: even debunkers will acknowledge that plenty of
beliefs have a causal history that is epistemically uninteresting. Perhaps there
will be an alternative, widely recognized epistemological vice that arises from the
evolutionary origins of ethical belief. But luck has been the focus of debunkers for
good reason: it is an uncontroversial condition on many epistemically interesting
notions, and assessing whether it is (or is not) present is often straightforward.
How the debunker might accomplish this task while explicitly eschewing talk of
luck is unclear, as epistemology is a contentious area, and there are not many
alternatives that will enjoy widespread acceptance. Regardless of the outcome,
extended reflection on the role of luck in evolutionary debunking arguments
points to some directions which are dead ends for debunkers, sheds light on
directions in which a successful argument might be developed, and imposes
significant constraints on what would constitute success for the debunker.
