Cross-ratio dynamics and the dimer cluster integrable system

Niklas Affolter  Terrence George  Sanjay Ramassamy

August 28, 2021

Abstract

Cross-ratio dynamics, allowing to construct 2D discrete conformal maps from 1D initial data, is a well-known discrete integrable system in discrete differential geometry. We relate it to the dimer integrable system from statistical mechanics by identifying its invariant Poisson structure and integrals of motion recently found by Arnold et al. to the Goncharov-Kenyon counterparts for the dimer model on a specific class of graphs. This solves the open question of finding a cluster algebra structure describing cross-ratio dynamics. The main tool relating geometry to the dimer model is the definition of triple crossing diagram maps associated to bipartite graphs on the cylinder. In passing we write the bivariate polynomial defining the dimer spectral curve for arbitrary bipartite graphs on the torus as the characteristic polynomial of a one-parameter family of matrices, a result which may be of independent interest.

1 Introduction

Consider maps \( f : \mathbb{Z}^2 \to \mathbb{C} \mathbb{P}^1 \) such that

\[
\frac{(f_{i,j} - f_{i+1,j})(f_{i+1,j+1} - f_{i,j+1})}{(f_{i+1,j} - f_{i+1,j+1})(f_{i,j+1} - f_{i,j})} = \alpha_j,
\]

where \( \alpha_j \in \mathbb{C} \setminus \{0\} \) and all \( i, j \in \mathbb{Z} \). Such a map is a special case of a discrete version of the Schwarzian KdV equation [NC95], or a special case of a discrete isothermic surface [BP96] restricted to the sphere \( S^2 \). In both cases it was shown that these maps are a discrete integrable system in the sense that they admit a discrete Lax representation. An interesting question is: Given all \( \alpha_j \), what is the space of solutions of (1)? To answer this, consider each column \( i \) of \( \mathbb{Z}^2 \) as a discrete curve \( f_i : \mathbb{Z} \to \mathbb{C} \mathbb{P}^1 \). The discrete curves corresponding to two adjacent columns \( f_i \) and \( f_{i+1} \) are called \( \vec{\alpha} \)-related, where \( \vec{\alpha} \) is the vector of all \( \alpha_j \). In the case when \( \alpha_j \) is independent of \( j \), the curve \( f_{i+1} \) is called a Darboux transform [HJ03] of \( f_i \) in the discrete differential geometry community. If we know \( f_i \) and one point of \( f_{i+1} \), then equation (1) determines all of \( f_{i+1} \). As a consequence, there is a complex one parameter freedom for each additional column of \( \mathbb{Z}^2 \). However, this changes if one considers periodic maps, that is maps \( \mathbb{Z} \times \mathbb{Z}/m\mathbb{Z} \to \mathbb{C} \mathbb{P}^1 \) for some \( m \in \mathbb{N} \) that satisfy equation (1). In this case, if we know \( f_i \) then there are only two possible solutions for \( f_{i+1} \), because \( f_{i+1} \) has to be periodic as well. Thus if we know both \( f_{i-1} \) as well as \( f_i \) and assume that \( f_{i+1} \neq f_{i-1} \), then \( f_{i+1} \) is determined uniquely. Special attention has been payed to the case that \( \alpha_j \) does not depend on \( j \). In this case, periodic solutions to equation (1) have been studied as periodic discrete conformal maps [HJMP01] with respect to algebro-geometric integrability. Also in this case, the map \( (f_{i-1}, f_i) \mapsto (f_i, f_{i+1}) \) is called cross-ratio dynamics [AFIT20]. Cross-ratio dynamics can also
be generalized from discrete periodic curves to discrete twisted curves, that is curves $f_i : \mathbb{Z} \to \mathbb{C}P^1$ such that $f_i(j + n) = M \circ f_i(n)$ for all $j \in \mathbb{Z}$ and for some $n \in \mathbb{N}$ and $M \in \text{PGL}_2$. For cross-ratio dynamics the integrability in the sense of Liouville was proved by Arnold, Fuchs, Izmestiev and Tabachnikov [AFIT20]. Indeed, they provide Poisson brackets that are preserved by the dynamics as well as integrals of motion that are Casimirs and Hamiltonians. We will henceforth call them the AFIT Poisson structures, Casimirs and Hamiltonians.

Another widely studied discrete system which is integrable both in the algebro-geometric sense and in the Liouville sense is the dimer model on bipartite graphs on the torus [GK13] coming from statistical mechanics. Goncharov and Kenyon identified a Poisson structure on the space of face weights associated to a given graph and obtained the Casimirs and Hamiltonians of the underlying integrable system as coefficients of the polynomial defining the spectral curve of the model. Our first main result consists in identifying the AFIT Liouville integrable structure [AFIT20] with the Goncharov-Kenyon Liouville integrable structure [GK13] for a special class of graphs. It is stated loosely in Theorem 1.1 below and stated in full detail as Theorem 6.7 and Theorem 7.1 later. Let $G$ (resp. $G^{odd}$) be the cylinder graph represented on the left (resp. right) of Figure 8. In both pictures, the top and the bottom sides of the rectangle are identified. If $n$ is even, let $\Gamma_n$ be the torus graph obtained by gluing in a cyclic chain $\frac{n}{2}$ copies of $G$. If $n$ is odd let $\Gamma_n$ be the torus graph obtained by gluing in a cyclic chain $\frac{n-1}{2}$ copies of $G$ and one copy of $G^{odd}$. See Figure 1 for pictures of $\Gamma_6$ and $\Gamma_5$. In this article we consider a more general setup than [AFIT20], namely we assume that the $\alpha_j$ are periodic of period $n$, but not necessarily constant.

**Theorem 1.1.** Let $n \geq 2$. The AFIT Poisson structure, Casimirs and Hamiltonians for cross-ratios dynamics for twisted discrete curves coincide with the Goncharov-Kenyon Poisson structure, Casimirs and Hamiltonians for the dimer integrable system on the torus graph $\Gamma_n$. 

In order to prove Theorem 1.1 we find an expression for the bivariate polynomial defining the dimer spectral curve for general bipartite graphs on the torus as the characteristic polynomial of a matrix depending on a single parameter. More precisely, given an edge-weighted bipartite graph
Γ on the torus, we construct a matrix \( \Pi(w) \) depending on a parameter \( w \) and on the choice of a zigzag path in \( \Gamma \). Then we have

**Theorem 1.2.** The spectral curve of the dimer model on \( \Gamma \) is given by

\[
\{(z, w) \in (\mathbb{C}^*)^2, \ det(zI - \Pi(w)) = 0\}
\]

Theorem 1.2 holds for general graphs and not just for those related to cross-ratio dynamics, hence it may be of independent interest. The matrix \( \Pi(w) \) is reminiscent of the boundary measurement matrix for networks on cylinders of \([\text{GSV12}, \text{GSTV16}]\). In a recent preprint of which we learned during the completion of this work, Izosimov \([\text{Izo21}]\) made precise the connection between the integrable systems of \([\text{GK13}]\) and \([\text{GSTV16}]\). In particular his main result provides a representation of the dimer spectral curve similar to Theorem 1.2. We note that analogous representations have appeared in physics in the special case of the periodic Toda chain \([\text{EFS12}]\) and in mathematical physics via representation-theoretic arguments \([\text{FM16}]\).

Theorem 1.1 realizes cross-ratio dynamics as a special case of the dimer integrable system by adopting an analytic point of view using coordinates on the spaces on which the two dynamics occur. One can actually provide a more geometric identification by making use of the recently introduced \([\text{AGR}]\) triple crossing diagram maps (TCD maps). These maps, a version of the vector-relaation configurations of \([\text{AGPR19}]\) better adapted to geometric dynamics, associate a geometric configuration in some projective space \(\mathbb{C}P^m\) to a bipartite graph on a disk with trivalent black vertices. To each white vertex is associated a point in \(\mathbb{C}P^m\), with the constraint that any three points associated to the neighbors of a black vertex must be aligned. One can perform local changes of the geometric configuration of a TCD map which are associated with the dimer local moves for bipartite graphs. Using appropriate coordinates, these moves carry an interpretation in terms of cluster algebra mutations.

In this article, we introduce the notion of twisted TCD maps on the cylinder. Let \( \Gamma_{n,\tilde{\alpha}} \) be the cylinder graph obtained by gluing together the same cylinder graphs as for \( \Gamma_n \) but without closing up cyclically (see Figure 1 for two examples). An explicit bridge between cross-ratio dynamics and the dimer model is given by the following result:

**Theorem 1.3.** Pairs of \( \tilde{\alpha} \)-related twisted discrete curves arise as twisted TCD maps on \( \Gamma_{n,\tilde{\alpha}} \) and cross-ratio dynamics arises as an explicit sequence of local moves on these twisted TCD maps.

An important note regarding Theorem 1.3 is that the first local move in the sequence depends on a parameter and that parameter depends globally on the initial pair of \( \tilde{\alpha} \)-related twisted discrete curves. Furthermore, combining Theorem 1.1 with Theorem 1.3, we obtain an alternative proof of the conservation of the AFIT Hamiltonians, since the dynamics on TCD maps is conjugated to the dimer integrable dynamics of \([\text{GK13}]\). A more explicit statement of Theorem 1.3 is given by Theorem 8.2. As a corollary, we answer an open question of \([\text{AFIT20}]\) asking for an interpretation of cross-ratio dynamics in terms of cluster algebras. Indeed, all but the first and the last operations for TCD maps of Theorem 1.3 has a cluster algebra interpretation \([\text{AGPR19}, \text{AGR}]\).

**Corollary 1.4.** The evolution of the some coordinates under cross-ratio dynamics can be written as an explicit composition of operations, with all but the first and the last one being cluster algebra mutations.

Here we mean mutations of cluster variables known as \( y \) \([\text{FZ02}]\) or as \( X \) \([\text{FG09}]\) depending on the authors.
As noted by [AFIT20], cross-ratio dynamics bears a lot of resemblances with the pentagram map, another dynamical system on discrete curves for which several similar properties are known: Liouville integrability [OST10, OST13], algebro-geometric integrability [Sol13], cluster algebra interpretation [Gli11], dimer model interpretation [FM16, GR17] and realization in terms of TCD maps [AGPR19, AGR]. Similar properties are known or expected to hold for many generalizations of the pentagram map, see e.g. [GP16].

There is however a notable difference with cross-ratio dynamics. For the pentagram map and its generalizations, the dynamics is local in the sense than one can construct a point of the curve $f_{i+1}$ knowing only a bounded number of points of the curve $f_i$. For cross-ratio dynamics the dynamics is global, one needs to know all the points of the curve $f_i$ to construct any given point of $f_{i+1}$. This is related to the R-matrix constructions of [ILP16, ILP19, Che20].

Organization of the paper

In Section 2 we provide the necessary background on cross-ratio dynamics and its integrability following mostly [AFIT20], but generalizing to $n$-periodic $\vec{\alpha}$. In Section 3 we recall the Goncharov-Kenyon integrable system [GK13] associated with the dimer model on the torus. In Section 4 we consider the dimer model on the cylinder, construct the matrix $\Pi(w)$ and prove Theorem 1.2. We introduce in Section 5 the notion of twisted TCD maps associated to a bipartite graph on the cylinder and use it in Section 6 to prove Theorem 1.1 when $n$ is even. In Section 7 we explain how to modify the computations to derive this result when $n$ is odd. Section 8 describes the sequence of local moves for twisted TCD maps that realize cross-dynamics, as stated in Theorem 1.3. Finally Appendix A presents some results used in Section 4 related to the classical Schur complement.

2 The cross-ratio dynamics integrable system

2.1 Multi-ratios

Given points $a_1, \ldots, a_{2m} \in \mathbb{C}P^1$, let $\tilde{a}_1, \ldots, \tilde{a}_{2m}$ denote a choice of lifts to $\mathbb{C}^2$. Their multi-ratio is defined as

$$\text{mr}(a_1, a_2, \ldots, a_{2m}) = \prod_{i=1}^{m} \frac{\text{det}(\tilde{a}_{2i-1}, \tilde{a}_{2i})}{\text{det}(\tilde{a}_{2i}, \tilde{a}_{2i+1})},$$

(2)

where $\text{det}(a, b)$ denotes the determinant of the matrix with columns $a, b \in \mathbb{C}^2$ and indices are taken modulo $2m$. When $m = 2$, the multi-ratio specializes to the cross-ratio

$$\text{cr}(a_1, a_2, a_3, a_4) = \frac{\text{det}(\tilde{a}_1, \tilde{a}_2) \text{det}(\tilde{a}_3, \tilde{a}_4)}{\text{det}(\tilde{a}_2, \tilde{a}_3) \text{det}(\tilde{a}_4, \tilde{a}_1)}.$$

(3)

The multi-ratio is $\text{PGL}_2$ invariant. If the points $a_i$ are all in an affine chart $\mathbb{C} \subset \mathbb{C}P^1$, then we can choose lifts of the form $\tilde{a}_i = \begin{bmatrix} a_i \\ 1 \end{bmatrix}$, and then we have

$$\text{mr}(a_1, a_2, \ldots, a_{2m}) = \prod_{i=1}^{m} \frac{a_{2i-1} - a_{2i}}{a_{2i} - a_{2i+1}}.$$

(4)
2.2 Discrete projective curves in $\mathbb{CP}^1$

A discrete curve is a map $p : \mathbb{Z} \to \mathbb{CP}^1$. A twisted discrete curve of length $n$ is a pair $(p, M)$ where $p : \mathbb{Z} \to \mathbb{CP}^1$ is a discrete curve and $M \in \text{PGL}_2$ is a projective transformation called monodromy such that $p_{i+n} = M(p_i)$ for all $i \in \mathbb{Z}$. A twisted discrete curve $(p, M)$ is nondegenerate if for all $i \in \mathbb{Z}$, we have $p_i \notin \{p_i+1, p_i+2\}$, and closed if $M$ is the identity.

Let $\tilde{\mathcal{P}}_n$ denote the space of nondegenerate twisted discrete curves of length $n$. $\tilde{\mathcal{P}}_n$ is an open subvariety of $(\mathbb{P}^1)^n \times \text{PGL}_2$, and $\text{PGL}_2$ acts on it by

$$A \cdot (p_1, p_2, \ldots, p_n, M) = (A(p_1), A(p_2), \ldots, A(p_n), AMA^{-1}).$$

The quotient $\mathcal{P}_n := \tilde{\mathcal{P}}_n / \text{PGL}_2$ is the moduli space of nondegenerate twisted curves of length $n$.

Given $p \in \tilde{\mathcal{P}}_n$, we define the $c$-variables

$$c_i := \text{cr}(p_{i-1}, p_i, p_{i+2}, p_{i+1}) \text{ for all } i \in \mathbb{Z}. \quad (5)$$

Notice that $c_{i+n} = c_i$ for all $i \in \mathbb{Z}$. If $p$ is nondegenerate, $c_i(p) \notin \{0, \infty\}$, so the $c$-variables give us a morphism

$$c : \tilde{\mathcal{P}}_n \to (\mathbb{C}^\times)^n \quad (6)$$

$$p \mapsto (c_1, c_2, \ldots, c_n).$$

Since each $c_i$ is a cross-ratio, this morphism is PGL$_2$ invariant, and therefore descends to a morphism $c : \mathcal{P}_n \to (\mathbb{C}^\times)^n$. Given the $c$-variables and three initial points $p_1, p_2, p_3$, the whole discrete curve is recovered from (5). Since any three points can be mapped to any other three points by a projective transformation, the $c$-variables characterize a discrete curve up to projective transformations and so $c$ is an isomorphism. The inverse morphism is given explicitly in [AFT20, Section 3.2].

The following lemma gives an explicit representative for the PGL$_2$ conjugacy class of the monodromy matrix $M$ in terms of the $c$-variables.

**Theorem 2.1** ([AFT20 Lemma 3.2]).

$$M = \begin{bmatrix} 0 & c_1 & & \\ -1 & 0 & c_2 & \\ & -1 & 0 & \ddots \\ & & & -1 & 0 \end{bmatrix}$$

represents the monodromy matrix.

2.3 The Poisson variety $\mathcal{U}_n$. 

Let $\alpha = (\alpha_i)_{i \in \mathbb{Z}}$ with $\alpha_i \in \mathbb{C} \setminus \{0, 1\}$ such that $\alpha_{i+n} = \alpha_i$. Two discrete curves $p, q \in \tilde{C}_n$ are said to be $\alpha$-related, and denoted $p \sim_{\alpha} q$ if

$$\text{cr}(p_i, q_i, p_{i+1}, q_{i+1}) = \alpha_i \text{ for all } i \in \mathbb{Z}, \quad (7)$$

and $p$ and $q$ have the same monodromy. Note that condition (7) alone does not imply that $p$ and $q$ have the same monodromy. The relation $\sim_{\alpha}$ is PGL$_2$ invariant and therefore descends to a relation
on \( P_n \). If \( \alpha_i = \alpha \) for all \( i \), then we say that \( p \) and \( q \) are \( \alpha \)-related and write \( p \sim \alpha q \).

Let \( \widetilde{U}_n \) denote the space of pairs of \( \alpha \)-related nondegenerate twisted curves of length \( n \). It is a subvariety of \( (\mathbb{P}^1)^{2n} \times \text{PGL}_2 \) and \( \text{PGL}_2 \) acts on it by

\[
A \cdot (p_1, \ldots, p_n, q_1, \ldots, q_n, M) = (A(p_1), \ldots, A(p_n), A(q_1), \ldots, A(q_n), A M A^{-1}).
\]

We define the \( u \)-variables

\[
u_i = -cr(p_i, p_{i+1}, q_i, q_{i-1}) \quad \text{for all } i \in \mathbb{Z}. \tag{8}
\]

Since \( p \) and \( q \) are nondegenerate and \( \alpha \)-related, \( u_i \notin \{0, -1, \infty\} \). Therefore the \( u \)-variables define a \( \text{PGL}_2 \) invariant morphism \( u : \widetilde{U}_n \rightarrow (\mathbb{C} \setminus \{0, -1\})^n \) which descends to a morphism

\[
u : U_n := \widetilde{U}_n / \text{PGL}_2 \rightarrow (\mathbb{C} \setminus \{0, -1\})^n.
\]

Consider the morphism

\[
\rho : U_n \rightarrow P_n, \quad (p, q, M) \mapsto (p, M).
\]

**Remark.** \( \widetilde{U}_n \) and \( U_n \) also depend on \( \alpha \), but we suppress this dependence in the notation.

In [AFIT20] Section 4.8 it is shown that

\[
\begin{array}{ccc}
U_n & \xrightarrow{\rho} & P_n \\
\downarrow u & & \downarrow c \\
(\mathbb{C} \setminus \{0, -1\})^n & \xrightarrow{\Lambda \alpha} & (\mathbb{C}^\times)^n
\end{array}
\]

commutes, where the map \( \Lambda \alpha \) is determined by \( c_i = \frac{\alpha_i}{(1+u_i)(1+\frac{1}{u_i+1})} \). If we are given \( u \)-variables, we can recover \( p \) up to projective transformations as \( c^{-1} \circ \Lambda \alpha(u_1, \ldots, u_n) \), and \( q \) is then determined by \( u \). Therefore the morphism \( u \) induces an isomorphism between \( U_n \) and \( (\mathbb{C} \setminus \{0, -1\})^n \). The set \( U_n \) is the *moduli space of pairs of \( \alpha \)-related twisted discrete curves of length \( n \).*

The Poisson bracket

\[
\{u_i, u_{i+1}\}_U := u_i u_{i+1},
\]

makes \( (U_n, \{\cdot, \cdot\}_U) \) a Poisson variety while the Poisson bracket

\[
\{c_i, c_{i+1}\}_\alpha := c_i c_{i+1} \left(1 - \frac{c_i}{\alpha_i} - \frac{c_{i+1}}{\alpha_{i+1}}\right), \quad \{c_i, c_{i+2}\}_\alpha := -\frac{1}{\alpha_{i+1}} c_i c_{i+1} c_{i+2}, \tag{9}
\]

makes \( (P_n, \{\cdot, \cdot\}_\alpha) \) a Poisson variety. For both Poisson brackets, we only give the nonzero values obtained by pairing two coordinate functions. We also define the rescaled coordinates \( \tilde{c}_i := \frac{c_i}{\alpha_i} \). In these coordinates the Poisson bracket \( \{\cdot, \cdot\}_\alpha \) takes the simpler form

\[
\{\tilde{c}_i, \tilde{c}_{i+1}\} = \tilde{c}_i \tilde{c}_{i+1} (1 - \tilde{c}_i - \tilde{c}_{i+1}), \quad \{\tilde{c}_i, \tilde{c}_{i+2}\} = -\tilde{c}_i \tilde{c}_{i+1} \tilde{c}_{i+2}.
\]

A computation similar to [AFIT20] Lemma 3.9 shows that \( \rho \) is Poisson. [AFIT20] Corollary 2.7 shows that \( \rho \) is generically finite of degree 2, that is for a generic discrete curve \( p \in P_n \) there are
two discrete curves \(q, r \in \mathcal{P}_n\) that are \(\alpha\)-related to \(p\). Therefore the map \(T_{\alpha} : (p, q, M) \mapsto (p, r, M)\) is a birational involution of \(U_n\). \(U_n\) also has another involution \(j : (p, q, M) \mapsto (q, p, M)\) given in coordinates by

\[
\begin{align*}
    u_i &\mapsto v_i := \frac{1}{u_i \alpha_i - 1} = -cr(q_i, q_{i+1}, p_i, q_{i-1}).
\end{align*}
\]

### 2.4 Cross-ratio dynamics and integrability

Suppose \((q, M) \in \mathcal{P}_n\) such that \(|\rho^{-1}(q, M)| = 2\), and suppose \(p, r\) are the two discrete curves \(\alpha\)-related to \(q\). The birational automorphism \(\nu = T_{\alpha} \circ j : U_n \rightarrow U_n\)

\[
(p, q, M) \mapsto (q, r, M)
\]

is called cross-ratio dynamics.

For \(I \subset [n]\), let \(c_I := \prod_{i \in I} c_i\). Similarly we define \(\tau_I, \alpha_I, u_I\) etc. Let \(c_{\text{even}} := c_2 c_4 \ldots\) and \(c_{\text{odd}} := c_1 c_3 \ldots\) denote the product of the even and odd \(c\) variables respectively. In the same way, we define \(\alpha_{\text{even}}\) etc.

\(I \subset [i, j]\) is said to be cyclically sparse if it contains no pair of consecutive indices where the indices are taken periodic modulo \(n\). Define

\[
F_k(c) = \sum_{I \text{ cyclically sparse}; |I| = k} c_I \quad \text{for } k = 0, \ldots, \lfloor \frac{n}{2} \rfloor,
\]

\[
E_{\alpha} = \frac{1}{c_{[n]}} \left( \sum_{k=0}^{\lfloor \frac{n}{2} \rfloor} (-1)^k F_k(c) \right)^2.
\]

**Theorem 2.2 ([AFIT20, Main Theorem 1]).** We have:

1. For \(n\) even, \(\{\cdot, \cdot\}_{\alpha}\) has corank 2 and the subalgebra of Casimirs is generated by \(E_{\alpha}\) and \(c_{\text{even}}\).
2. For \(n\) odd, \(\{\cdot, \cdot\}_{\alpha}\) has corank 1 and the Casimir is \(E_{\alpha}\).
3. For \(k = 1, 2, \ldots, \lfloor \frac{n+1}{2} \rfloor - 1\), the functions \(\frac{F_k(c)}{c_{[n]}}\) mutually commute and form a maximal set of functionally independent Hamiltonians, making the Poisson variety \(\mathcal{P}_n\) a Liouville integrable system.

Moreover, cross-ratio dynamics is discrete integrable in the following sense:

1. \(\nu_{\alpha}\) is Poisson.
2. The pullbacks of the Hamiltonians and the Casimirs to \(U_n\) by \(\rho_{\alpha}\) are invariant under \(\nu_{\alpha}\).

The following theorem shows that the Hamiltonians can be obtained from the monodromy matrix.

**Theorem 2.3 ([AFIT20 Theorem 1]).** We have

\[
\frac{1}{\det M} \text{tr}^2 M = \frac{1}{c_{[n]}} \left( \sum_{k=0}^{\lfloor \frac{n}{2} \rfloor} (-1)^k F_k(c) \right)^2.
\]
Remark. Note that $\text{tr} M$ is not $\text{PGL}_2$ invariant, but the normalized trace $\frac{\text{tr} M}{\sqrt{\det M}}$ is. However the normalized trace is not a regular function on $\mathcal{P}_n$, so we need to square everything to make it so.

To get the Hamiltonians from Theorem 2.3, notice that $F_k(c)$ is the homogeneous degree $k$ component of $\frac{\sqrt{\text{tr} M}}{\sqrt{\det M}}$. This observation will be very useful in Section 6.2.

3 The dimer integrable system

For further details on this section, see [GK13].

3.1 The dimer model in a torus.

Let $\Gamma = (B \cup W, E)$ be a bipartite graph embedded in a torus $\mathcal{T}$ such that $|B| = |W|$ and such that the faces of $\Gamma$, that is, the connected components of the complement of $\Gamma$, are disks. We denote by $F$ the set of faces of $\Gamma$. An edge weight on $\Gamma$ is a function $\text{wt} : E \to \mathbb{C}^\times$. Two edge weights $\text{wt}_1$ and $\text{wt}_2$ are said to be gauge equivalent if there is a function $g : B \cup W \to \mathbb{C}^\times$ such that for every edge $e = \{b, w\}$ with $b \in B, w \in W$, we have $\text{wt}_2(e) = \text{wt}_1(e)g(w)g(b)^{-1}$. Let $\mathcal{L}_\Gamma$ denote the space of edge weights modulo gauge equivalence.

Equivalently, we can consider the graph $\Gamma$ as a cell complex whose 0 and 1-cells are $B$ and $E$ respectively. Considering each edge $e = bw$ to be oriented from $b$ to $w$, we have the nonzero cellular chain groups

$$C_0(\Gamma, \mathbb{Z}) = \mathbb{Z}B \oplus \mathbb{Z}W, \quad C_1(\Gamma, \mathbb{Z}) = \mathbb{Z}E,$$

with boundary homomorphism $\partial : C_1(\Gamma, \mathbb{Z}) \to C_0(\Gamma, \mathbb{Z})$ given by $\partial(e) = w - b$, so that $H_1(\Gamma, \mathbb{Z}) = \text{Ker} \partial$. Dually, we have cellular cochain groups $C^q(\Gamma, \mathbb{C}^\times) := \text{Hom}_\mathbb{Z}(C_q(\Gamma, \mathbb{Z}), \mathbb{C}^\times)$, for $q \in \{0, 1\}$, with coboundary homomorphism $\delta : C^0(\Gamma, \mathbb{C}^\times) \to C^1(\Gamma, \mathbb{C}^\times)$ given by $\delta(g)(e) = \frac{g(e)}{g(b)}$. Since an edge weight is a 1-cochain and two edge weights are gauge equivalent if and only if they differ by a 1-coboundary, we have

$$\mathcal{L}_\Gamma = H^1(\Gamma, \mathbb{C}^\times) := \frac{C^1(\Gamma, \mathbb{C}^\times)}{\delta(C^0(\Gamma, \mathbb{C}^\times))} \tag{13}$$

. We denote by $[\text{wt}]$ the cohomology class represented by the cochain $\text{wt}$.

For $[L] \in H_1(\Gamma, \mathbb{Z})$, we denote by $[\text{wt}]([L])$ the result of evaluating the cohomology class $[\text{wt}]$ on the homology class $[L]$ yielding an alternating product of edge weights around $L$. Explicitly, if the $L$ is the 1-cycle $w_1 \xrightarrow{e_1} b_1 \xrightarrow{e_2} w_2 \xrightarrow{e_3} b_2 \xrightarrow{e_4} \cdots w_n \xrightarrow{e_2n-1} b_n \xrightarrow{e_{2n}} w_1 \in H_1(\Gamma, \mathbb{Z})$, we have

$$[\text{wt}]([L]) = \prod_{i=1}^n \frac{\text{wt}(e_{2i-1})}{\text{wt}(e_{2i})}.$$

Since $\mathcal{L}_\Gamma = \text{Hom}_\mathbb{Z}(H_1(\Gamma, \mathbb{Z}), \mathbb{C}^\times)$ is an algebraic torus, the algebra $\mathcal{O}_{\mathcal{L}_\Gamma}$ of regular functions on $\mathcal{L}_\Gamma$ consists of the characters $\chi_{[L]}$ for $[L] \in H_1(\Gamma, \mathbb{Z})$ defined by $\chi_{[L]}([\text{wt}]) := [\text{wt}]([L])$.

We now give a description of $\mathcal{O}_{\mathcal{L}_\Gamma}$ in terms of a basis. For a face $f$ of $\Gamma$, let $\partial f$ denote the counterclockwise oriented cycle given by the walk along the boundary of $f$. Let $a$ and $b$ denote two cycles in $\Gamma$ generating $H_1(\mathcal{T}, \mathbb{Z})$. Let $X_f := \chi_{[\partial f]}$. Then

$$\mathcal{O}_{\mathcal{L}_\Gamma} = \mathbb{C}[X_f^\pm 1, X_a^\pm 1, X_b^\pm 1]/(1 - \prod_{f \in F} X_f), \tag{14}$$

where the relation $\prod_{f \in F} X_f = 1$ comes from the relation $\sum_{f \in F} \partial f = 0$ in $H_1(\Gamma, \mathbb{Z})$. 

8
Figure 2: The building block graph $G_i$, which is a graph on a cylinder, since the top and bottom sides of the rectangle are identified. Each face is labeled by its face weight.

Example 3.1. For $n$ even, consider the graph $\Gamma_n$ in $T$ for which a fundamental domain is obtained by gluing the cylinder graphs $G_i$ shown in Figure 2 for $i \in \{1, 2, \ldots, \frac{n}{2}\}$ in the order $G_1G_2 \cdots G_{\frac{n}{2}}$, so that $w_{2n+1}$ is identified with $w_1$ and $w_{2n+2}$ with $w_2$. The faces of $\Gamma_n$ are labeled by $X_i,Y_i$ for $i \in \{1, 2, \ldots, n\}$ as shown in Figure 2.

Zig-zag paths and Newton polygon. A zig-zag path in $\Gamma$ is a path that turns maximally left at white vertices and maximally right at black vertices. Let $Z$ denote the set of zig-zag paths of $\Gamma$. Each zig-zag path $\beta \in Z$ defines a homology class $[\beta] \in H_1(T,\mathbb{Z})$. Label the zig-zag paths $\beta_1, \beta_2, \ldots, \beta_{|Z|}$ so that the $[\beta_i]$ regarded as vectors in $H_1(T,\mathbb{Z}) \otimes \mathbb{R} \cong \mathbb{R}^2$ are in counterclockwise order. We construct a closed convex integral polygon $N(\Gamma)$ (or just $N$ when $\Gamma$ is clear from the context) by placing the $[\beta_i]$ such that the head of $[\beta_i]$ is the tail of $[\beta_{i+1}]$. Each edge of $\Gamma$ is contained in two zig-zag paths that traverse the edge in opposite directions, so we have $\sum_{\beta \in Z} [\beta] = 0$, which shows that $N$ constructed as above is a closed polygon. $N$ is unique up to translation and is called the Newton polygon of $\Gamma$. The name Newton polygon will be justified at the end of this section by that fact that this polygon arises as the Newton polygon of the characteristic polynomial. By construction, the set of primitive edge vectors of $N$ is in bijection with $Z$, but this bijection is not canonical when there is more than one zig-zag path with the same homology class.

A graph $\Gamma$ is said to be minimal if any lift of a zig-zag path to the universal cover of $T$ has no self intersections and any lifts of two zig-zag paths to the universal cover of $T$ do not form parallel bigons (pairs of zig-zag paths oriented the same way intersecting twice).
Example 3.2. The graph $\Gamma_n$ has $n + 4$ zig-zag paths:

$$\begin{align*}
\xi_1 &= w_1, b_1, w_3, b_3, \ldots, w_{2n-1}, b_{2n-1}, w_1, \quad [\xi_1] = (1, 0), \\
\xi_2 &= w_1, b_{2n-1}, w_{2n}, b_{2n-3}, \ldots, w_4, b_1, w_1, \quad [\xi_2] = (-1, 0), \\
\xi_3 &= w_2, b_2, w_4, b_4, \ldots, w_{2n}, b_{2n}, w_2, \quad [\xi_3] = (1, 0), \\
\xi_4 &= w_2, b_{2n}, w_{2n-1}, b_{2n-2}, \ldots, w_3, b_2, w_2, \quad [\xi_4] = (-1, 0), \\
\zeta_{2i-1} &= w_{4i-1}, b_{4i-3}, w_{4i}, b_{4i-2}, w_{4i-1}, \quad [\zeta_{2i-1}] = (0, 1), \\
\zeta_{2i} &= w_{4i-1}, b_{4i}, w_{4i+1}, b_{4i-1}, w_{4i-1}, \quad [\zeta_{2i}] = (0, -1),
\end{align*}$$

where $i \in \{1, 2, \ldots, \frac{n}{2}\}$ and we use the basis $(\gamma_x, \gamma_y)$ to identify $H_1(\mathbb{T}, \mathbb{Z})$ with $\mathbb{Z}^2$ (see Figure 5 for the case $n = 1$). Therefore the Newton polygon of $\Gamma_n$ is (see Figure 3):

$$\text{Convex-hull } \{ (0, 0), (2, 0), \left(0, \frac{n}{2}\right), \left(2, \frac{n}{2}\right) \}.$$

It is easily checked that $\Gamma_n$ is minimal.

Conjugate surface and Poisson structure. Thickening the edges of $\Gamma$, we obtain a ribbon graph. Equivalently a ribbon graph is a graph along with the data of a cyclic order of edges around each vertex. The ribbon graph obtained from $\Gamma$ has the cyclic order induced from the embedding in $\mathbb{T}$. Let $\tilde{\Gamma}$ be the ribbon graph obtained from $\Gamma$ by reversing the cyclic order at all white vertices. The boundary components of $\tilde{\Gamma}$ are in bijection with the zig-zag paths of $\Gamma$. Gluing in disks along these boundary components of $\tilde{\Gamma}$, we obtain a surface $\tilde{S}$ called the conjugate surface, along with an embedding of $\Gamma$ in $\tilde{S}$. Let $\epsilon_{\tilde{S}}$ denote the intersection form on $H_1(\tilde{S}, \mathbb{Z})$: For $[L_1], [L_2] \in H_1(\tilde{S}, \mathbb{Z})$, choose cycles $L_1$ and $L_2$ representing the homology classes and intersecting transversely. Then

$$\epsilon_{\tilde{S}}([L_1], [L_2]) = \sum_{p \in L_1 \cap L_2} \epsilon_p(L_1, L_2), \quad (15)$$

where $\epsilon_p(L_1, L_2)$ is the local intersection index, with sign chosen so that it is positive if $L_2$ crosses $L_1$ at $p$ from its right side to its left side. The embedding $\iota : \Gamma \hookrightarrow \tilde{S}$ induces the homomorphism

![Newton polygon of $\Gamma_n$ for even $n$ (left) and odd $n$ (right).](image-url)
of homology groups $\iota_* : H_1(\Gamma, \mathbb{Z}) \rightarrow H_1(\hat{S}, \mathbb{Z})$. We define the alternating form $\epsilon_\Gamma$ on $H_1(\Gamma, \mathbb{Z})$ by

$$\epsilon_\Gamma([L_1], [L_2]) := \epsilon_{\hat{S}}(\iota_* [L_1], \iota_* [L_2]).$$

For $[L_1], [L_2] \in H_1(\Gamma, \mathbb{Z})$, define the Poisson bracket

$$\{ \chi_{[L_1]}, \chi_{[L_2]} \}_\Gamma := \epsilon_\Gamma([L_1], [L_2]) \chi_{[L_1]} \chi_{[L_2]}.$$ (16)

The faces of $\Gamma$ in $\hat{S}$ become the zig-zag paths of $\Gamma$ in $T$, so we have $\{ \chi_{[L_1]}, \chi_{[L_2]} \}_\Gamma = 0$ for all $[L_2]$ if and only if $[L_1] \in \bigoplus_{\beta \in \mathbb{Z}} \mathbb{Z} \cdot [\beta]$. Therefore the functions $C_\beta := \chi_{[\beta]}, \beta \in \mathbb{Z}$ generate the center of the Poisson algebra $\mathcal{O}_{\mathcal{L}_\Gamma}$. These functions are called Casimirs.

**Elementary transformations and mutations.** There are two local modifications of bipartite graphs called elementary transformations shown in Figure 7. An elementary transformation $s : \Gamma \rightarrow \Gamma'$ induces a unique up to isotopy homeomorphism of conjugate surfaces $\hat{s} : \hat{S}_\Gamma \rightarrow \hat{S}_{\Gamma'}$ [GK13, Lemma 4.1], which in turn induces an isomorphism $\hat{s}_* : H_1(\Gamma, \mathbb{Z}) \rightarrow H_1(\Gamma', \mathbb{Z})$. Associated to the elementary transformation $s$ is a Poisson birational map of weights $\mu_s : \mathcal{L}_\Gamma \rightarrow \mathcal{L}_{\Gamma'}$:

1. The spider move $s$ at face $f$: For $[L'] \in H_1(\Gamma', \mathbb{Z})$, let $[L] = (\hat{s}_*)^{-1}([L'])$. We define

$$\mu^*_s(\chi_{[L']}) = \chi_{[L]}(1 + X_f^{-\text{sign} \epsilon_\Gamma([L], \partial f)})^{-\epsilon_\Gamma([L], \partial f)}.$$ (17)

2. Shrinking/expanding degree two vertices: We define $\mu^*_s(\chi_{[L']}) = \chi_{[L]}$.

Since elementary transformations are local, they do not change homology classes of zig-zag paths, and therefore the Newton polygon. Gluing the Poisson affine varieties $\mathcal{L}_\Gamma$ for all $\Gamma$ minimal with $N(\Gamma) = N$ using these Poisson birational maps, we obtain the Poisson space $\mathcal{X}_N$ called the dimer cluster Poisson variety associated to $N$. $\mathcal{X}_N$ is a cluster Poisson variety as defined by Fock and Goncharov [FG09], and will be the phase space of the dimer integrable system.

![Figure 4: Adding/removing a bigon inside a face.](image)

**Inserting/removing a bigon.** Figure 4 shows the insertion of a bigon between vertices $w \in W$ and $b \in B$ belonging to a common face $f$, with parameter $t$. This divides $f$ into three new faces, the bigon $f_b$ and the face $f_l$ (resp. $f_r$) to the left (resp. right) of $f_b$ when traversing the bigon from $w$ to $b$. Let $\Gamma_b$ denote the graph obtained. The embedding $i_b : \Gamma \rightarrow \Gamma_b$ induces a homomorphism $(i_b)_* : H_1(\Gamma, \mathbb{Z}) \rightarrow H_1(\Gamma_b, \mathbb{Z})$. We define the induced map of weights $\mu_t : \mathcal{L}_\Gamma \rightarrow \mathcal{L}_{\Gamma_b}$.
Figure 5: Edge weights, Kasteleyn sign and $M_0$ (thick edges) on $\Gamma_2$.

on a basis as follows: If $[L]$ is topologically nontrivial in $H_1(\mathbb{T},\mathbb{Z})$ or is the boundary of a face of $\Gamma$ set $\mu^*_i(\chi(b),[L]) = \chi(L)$. Define also $\mu^*_i(X_{fb}) = t$ and $\mu^*_i(X_{fb}) = -1$. Note that the second equation implies that in any cocycle, the weights of the two edges of the bigon sum to zero. On the other hand, if we have bigon with $X_{fb} = -1$, we may remove it. This induces a map of weights $\mu'_b : \{X_{fb} = -1\} \rightarrow L_\Gamma$, where $\{X_{fb} = -1\}$ denotes the subvariety in $L_\Gamma$, given by $\mu^*_b(\chi[L]) = \chi(b),[L]$.

3.2 Dimer covers and Kasteleyn theory.

A dimer cover $M$ of $\Gamma$ is a subset of $E$ such that each vertex of $\Gamma$ is incident to exactly one edge in $M$. Let $M$ denote the set of dimer covers of $\Gamma$. If we fix a reference dimer cover $M_0$, then we can associate to each dimer cover a homology class $M \mapsto [M - M_0] \in H_1(\mathbb{T},\mathbb{Z})$, where as before we orient $e = \{b,w\}$ from $b$ to $w$. Given $[wt] \in L_\Gamma$, each dimer cover also gets a weight $[wt](M - M_0)$. If $\Gamma$ is minimal, we can describe the Newton polygon in terms of dimer covers.

**Proposition 3.3 (GK13 Theorem 3.12).** For a minimal bipartite graph $\Gamma$ in $\mathbb{T}$, we have

$$N(\Gamma) = \text{Convex-hull} \{[M - M_0] : M \text{ is a dimer cover of } \Gamma\},$$

up to a translation.

Let $R$ be a fundamental rectangle of $\mathbb{T}$ and let $\gamma_z, \gamma_w$ be cycles in $\mathbb{T}$ such that $[\gamma_z], [\gamma_w]$ generate $H_1(\Gamma,\mathbb{Z})$. We choose $\gamma_z, \gamma_w$ parallel to the sides of $R$ as shown in Figure 5. Isotoping if necessary, we assume that the edges of $\Gamma$ intersect $\gamma_z, \gamma_w$ transversely. Applying $\text{Hom}_\mathbb{C}(\cdot,\mathbb{C}^\times)$ to the surjection
\[ H_1(\Gamma, \mathbb{Z}) \to H_1(T, \mathbb{Z}) \], we get an inclusion \( H^1(T, \mathbb{C}^\times) \hookrightarrow H^1(\Gamma, \mathbb{C}^\times) \). Let \([\phi'] \in H^1(\Gamma, \mathbb{C}^\times)\) be in the image of \( H^1(T, \mathbb{C}^\times) \). In other words, \( X_f([\phi']) = 1 \) for all \( f \in F \). We choose a cochain \( \phi \) representing \([\phi']\) as follows: Let \( z := [\phi'][(\gamma_z)], w = [\phi'][(\gamma_w)] \), and define
\[
\phi(e) := z^{(e, \gamma_w)} w^{(e, -\gamma_z)},
\]
where \((\cdot, \cdot)\) is the intersection index.

[\([\kappa] \in H^1(\Gamma, \mathbb{C}^\times)\) is called a Kasteleyn sign if

1. \( X_L([\kappa]) = \pm 1 \) for all \([L] \in H_1(\Gamma, \mathbb{Z})\).

2. \( X_f([\kappa]) = (-1)^{|\partial f|} \) for all \( f \in F \), where \(|\partial f|\) is the number of edges in \( \partial f \).

Let \( \kappa : E \to \mathbb{C}^\times \) be a cochain representing the Kasteleyn sign \([\kappa]\). We define the Kasteleyn matrix
\[
K(z, w) : \mathbb{C}[z^{\pm 1}, w^{\pm 1}]^B \to \mathbb{C}[z^{\pm 1}, w^{\pm 1}]^W
\]
by
\[
K(z, w)_{w, b} := \sum_{e = (b, w) \in E} \text{wt}(e) \kappa(e) \phi(e).
\]

**Theorem 3.4 ([Kas63]).** We have
\[
\frac{1}{\text{wt}(M_0) \kappa(M_0) \phi(M_0)} \det K(z, w) = \sum_{M \in \mathcal{M}} \text{sign}([M - M_0]) \text{wt}([M - M_0]) \phi([M - M_0]),
\]
where \( \text{sign}([M - M_0]) \) is a sign that depends on \([\kappa]\) and is irrelevant for our purposes.

Moreover,
\[
P(z, w) := \frac{1}{\text{wt}(M_0) \kappa(M_0) \phi(M_0)} \det K(z, w)
\]
is called the characteristic polynomial and \( \Sigma := \{(z, w) \in (\mathbb{C}^\times)^2 : P(z, w) = 0\} \) is called the spectral curve of \((\Gamma, [\kappa])\). Although \( K(z, w) \) depends on the choice of cochains representing \([\kappa]\) and \([\kappa]\), the spectral curve is independent of these choices. Moreover \( N(\Gamma) \) is the Newton polygon of \( P(z, w) \), that is, the convex hull of the pairs \((i, j) \in \mathbb{Z}^2\) such that \( z^i w^j \) has a nonzero coefficient in \( P(z, w) \).

**Example 3.5.** Consider the graph \( \Gamma_2 \) with edge-weights, Kasteleyn sign, \( \phi \) and reference dimer cover \( M_0 \) as shown in Figure 5. The Kasteleyn matrix is
\[
K(\Gamma_2) = \begin{bmatrix}
b_1 & b_2 & b_3 & b_4 \\
1 & 0 & z & 0 \\
0 & 1 & 0 & z \\
g & -bw & h & aw \\
-f & c & e & d
\end{bmatrix} \begin{bmatrix}
w_1 \\
w_2 \\
w_3 \\
w_4
\end{bmatrix},
\]
and the spectral curve is
\[
P(z, w) = \frac{1}{b f z^2 w} \left(-dh + (dg + ch)z - cgz^2 + aew + (be + af)zw + bf z^2 w\right).
\]
Hamiltonians. Let $N^\circ$ denote the interior of $N$. For $[\gamma] \in N^\circ \cap H_1(\Gamma, \mathbb{Z})$, let

$$H_{[\gamma]} := \sum_{M \in \mathcal{M} : [M - M_0] = [\gamma]} [\mathfrak{w}(M - M_0)]$$

denote the coefficient of $[\phi](\gamma)$ (up to a sign) in $P(z, w)$.

Proposition 3.6 ([GK13, Theorem 1.2]). The generic level sets of the Casimirs are symplectic leaves of $\mathcal{X}_N$. The Hamiltonians $H_{[\gamma]}$ for $[\gamma] \in H_1(T, \mathbb{Z}) \cap N^\circ$ mutually commute, making these symplectic leaves into algebraic integrable systems.

4 The dimer model in a cylinder

Let $\Gamma_A = (B \cup W, E)$ be a bipartite graph embedded in a cylinder $A$ such that:

1. The faces of $\Gamma_A$ (including boundary faces) are disks.
2. Every vertex on the boundary of $A$ is white and of degree 1.
3. Let $S$ and $T$ denote the boundary white vertices on the two components of the boundary of $A$, called the source and target vertices respectively. Let $W_{int} = W \setminus (S \cup T)$ denote the set of internal white vertices. We assume that $|S| = |T|$ and $|B| = |W| - |S|$.
4. $\Gamma_A$ has a dimer cover $M_0$ that uses all the vertices in $S$ and none of the vertices in $T$.

Here by a dimer cover of $\Gamma_A$, we mean a matching that uses all the vertices in $B$ and a in $|B|$-element subset of $W$ exactly once. Note that assumptions 2 and 4 imply that the black vertices incident to the white vertices in $S$ are all different. We call graphs $\Gamma_A$ satisfying these conditions balanced cylinder graphs.

An edge-weight on $\Gamma_A$ is a function $\mathfrak{w} : E \to \mathbb{C}^\times$. Two edge weights $\mathfrak{w}_1$ and $\mathfrak{w}_2$ are gauge equivalent if there is a function $g : B \cup W \to \mathbb{C}^\times$ satisfying $g(w) = 1$ for all $w \in S \cup T$ such that for every edge $e = \{b, w\}$ with $b \in B, w \in W$, we have $\mathfrak{w}_2(e) = g(b)^{-1} \mathfrak{w}_1(e) g(w)$. In other words we only allow gauge transformations at interior vertices. The space of edge-weights modulo gauge transformations is the relative cohomology group $H^1(\Gamma_A, S \cup T, \mathbb{C}^\times)$. As before, we denote by $[\mathfrak{w}]$ the cohomology class represented by $\mathfrak{w}$.

Let $\mathcal{M}$ denote the set of dimer covers of $\Gamma_A$. For $M \in \mathcal{M}$, we define its weight to be $\mathfrak{w}(M) = \prod_{e \in E} \mathfrak{w}(e)$. For $M \in \mathcal{M}$, let $\partial M$ denote the set of boundary white vertices incident to $M$. For example, $\partial M_0 = S$.

4.1 Torus to cylinder

In this section, we outline a general procedure to construct a graph $\Gamma_A$ in a cylinder satisfying the assumptions in Section 3 from a graph $\Gamma$ in a torus $T$. Let $\beta$ be a zig-zag path in $\Gamma$. Without loss of generality, we assume that there are no 2-valent black vertices in $\beta$. Changing the fundamental domain if necessary, we can assume that $[\beta] = [\gamma_w]$. Split each black vertex in $\beta$ to create a 2-valent white vertex. $[\gamma_w]$ has a representative cycle $\gamma_w$ in $T$ that goes through each of the newly created 2-valent white vertices and does not intersect $\Gamma$ anywhere else. Cutting $T$ along $\gamma_w$, we obtain a cylinder $A$ and a graph $\Gamma_A$ embedded in it. The 2-valent white vertices become $S$ and $T$, where $T$
Figure 6: Cutting along a zig-zag path and labeling of vertices in $\Gamma_{ST}$. Removing the shaded region from $T$, we get $A$.

is connected to $\beta$ (see Figure 6). Since $|B(\Gamma)| = |W(\Gamma)|$, we have $|B(\Gamma_{\lambda})| = |W(\Gamma_{\lambda})| - |S|$. There is a dimer cover $M_0$ in $\Gamma$ that contains half the edges in $\beta$ (see for example [GK13, Theorem 3.12]), which becomes a dimer cover in $\Gamma_{\lambda}$ such that $\partial M_0 = S$.

### 4.2 Kasteleyn theory in $A$

Suppose $\Gamma_{\lambda}$ is a balanced cylinder graph. An element $[\kappa] \in H^1(\Gamma_{\lambda}, S \cup T, \mathbb{C}^\times)$ is called a Kasteleyn sign if

1. $X_L([\kappa]) = \pm 1$ for all $[L] \in H_1(\Gamma_{\lambda}, S \cup T, \mathbb{Z})$.

2. $X_f([\kappa]) = (-1)^{|\partial f| + 1}$ for all $f \in F$, where $|\partial f|$ is the number of edges in $\partial f$.

The existence of a Kasteleyn sign is shown in [CR08]. Moreover there is the following version of Kasteleyn’s theorem:

**Theorem 4.1** ([CR08, Theorem 2.4]). Let $I \subset S \cup T$ such that $|I| = |S|$, and let $K_{\lambda,I}$ denote the submatrix of the Kasteleyn matrix with rows indexed by white vertices in $I \cup W_{int}$ and columns indexed by black vertices in $B$. Then we have

$$\frac{1}{\text{wt}(M_0)\kappa(M_0)} \det K_{\lambda,I} = \sum_{\partial M = I} \text{sign}([M - M_0])\text{[wt]}([M - M_0]),$$

where $[M - M_0]$ is the relative homology class in $H_1(A, \partial A, \mathbb{Z})$ defined by the relative cycle $M - M_0$.

Let $B_S$ denote the set of black vertices incident to $S$. $B_S$ is matched to $S$ by $M_0$. The Kasteleyn
matrix $K_A$ of $\Gamma_A$ has the block matrix form

$$K_A = \begin{bmatrix} B_S & B \setminus B_S \\ I & 0 \\ K_1 & K_2 \\ K_3 & K_4 \end{bmatrix} \begin{bmatrix} S \\ T \\ \text{int} \end{bmatrix}. \quad (19)$$

For generic $[\text{wt}]$, $K_4$ is invertible using Theorem 4.1 with $I = S$, since $M_0$ is a dimer cover with $\partial M_0 = S$ that will appear as a summand in $\det K_4 = \det K_A$. Define the Schur complement

$$L := K_A / K_4 = \begin{bmatrix} I \\ K_1 \\ 0 \\ K_2 \end{bmatrix} K_4^{-1} K_3 = \begin{bmatrix} I \\ \Pi \end{bmatrix}, \quad (20)$$

where $\Pi := K_1 - K_2 K_4^{-1} K_3$. To get an explicit formula for the entries of $\Pi$, notice that for $w_i \in S, w_j \in T$, the square submatrix $L_{S \setminus \{w_i\} \cup \{w_j\}}$ of $L$ with rows indexed by $S \setminus \{w_i\} \cup \{w_j\}$ is the Schur complement $K_A_{S \setminus \{w_i\} \cup \{w_j\}} / K_4$. Using $\det K_4 = \det K_A$ and Theorem A.1, we have

$$\Pi_{w_j, b_i} = (-1)^{|S| - i} \det L_{S \setminus \{w_i\} \cup \{w_j\}} = (-1)^{|S| - i} \det \frac{K_A_{S \setminus \{w_i\} \cup \{w_j\}}}{K_A_{\text{int}}} = \frac{\det K_A_{S \setminus \{w_i\} \cup \{w_j\}}}{\det K_A_{\text{int}}}.$$

The $\Pi$ matrix has the following multiplicativity property that is useful for explicit computations.

**Proposition 4.2.** Suppose $\Gamma$ is a graph obtained by gluing graphs $\Gamma_i$ for $i = 1, \ldots, n$ from left to right, so that $S(\Gamma_i)$ is identified with $T(\Gamma_{i+1})$. Then

$$\Pi(\Gamma) = \Pi(\Gamma_1) \Pi(\Gamma_2) \cdots \Pi(\Gamma_n).$$

Here $S(\Gamma_i)$ and $T(\Gamma_{i+1})$ denote the source vertices of $\Gamma_i$ and target vertices of $\Gamma_{i+1}$ respectively.

We omit the proof since it is very similar to that of Theorem 4.4.

**Remark.** The matrix $\Pi$ is closely related to the boundary measurement matrix of [GSTV16]. The reference dimer $M_0$ makes $\Gamma_A$ into a directed network $\mathcal{N}$ as follows: Orient each edge $e = bw$ contained in $M_0$ from $w \to b$, and assign it weight $\frac{1}{\text{wt}(e)}$, and each edge not contained in $M_0$ from $w \to b$ and assign it weight $\text{wt}(e)$. Each directed path in $\mathcal{N}$ gets a weight that is the product of weights of all edges appearing in it. Then using Theorem 4.1, we have

$$1 = \frac{1}{\text{wt}(M_0) \kappa(M_0)} \det K_A = (-1)^{|S| - i} \det \frac{K_A_{S \setminus \{w_i\} \cup \{w_j\}}}{\text{wt}(M_0) \kappa(M_0)} = (-1)^{|S| - i} \sum_{\partial M = S \setminus \{w_i\} \cup \{w_j\}} \text{sign}([M - M_0]) [\text{wt}([M - M_0])] = \sum_{\partial M = S \setminus \{w_i\} \cup \{w_j\}} \text{sign}([M - M_0]) [\text{wt}([M - M_0])].$$

Notice that if $\partial M = S \setminus \{w_i\} \cup \{w_j\}$, then $M - M_0$ is a directed path in $\mathcal{N}$ from $w_i$ to $w_j$, so $1 = \frac{1}{\text{wt}(M_0) \kappa(M_0)} \det K_A = \text{boundary measurement matrix of } \mathcal{N}$. This is the reason for calling $S$ and $T$ the source and target vertices respectively.
**Example 4.3.** Consider the graph $\Gamma_2$ from Figure 5. Let $\Gamma_{A,2}$ denote the graph in the cylinder obtained from $\Gamma_2$ by applying the construction in Section 4.1 with the zig-zag path $\zeta_2$. In this case, we simply cut along the vertical side of the fundamental rectangle. The sources are the two white vertices $w_1$ and $w_2$ on the right boundary, while the targets are their copies on the left boundary that we denote by $w_5$ and $w_6$. The set $B_S$ is $\{b_3, b_4\}$. The Kasteleyn matrix is

$$ K_A = \begin{bmatrix} b_3 & b_4 & b_1 & b_2 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} w_1 \\ w_2 \\ w_5 \\ w_6 \end{bmatrix}, $$

and

$$ \Pi = \frac{1}{bf - cg} \begin{bmatrix} ch + be & ac + bd \\ eg + fh & dg + af \end{bmatrix}. \quad (21) $$

### 4.3 Spectral curve of $\Gamma$ from $\Gamma_A$. 

We now show how the spectral curve of $\Gamma$ can be constructed from $\Gamma_A$. In $\Gamma$, split the white vertices that are in the image of $S$ and $T$ under the projection of $\Gamma_A$ to $T$, so that we now have two copies of these white vertices which we identify with $S$ and $T$ respectively, connected by degree two black vertices. Let $\Gamma_{ST}$ denote the graph obtained. Let $B_{ST}$ denote the newly created degree two black vertices. Perturb $\gamma_w$ so that it goes transversely through all the edges connecting $B_{ST}$ with $T$ (see Figure 6). Let $\kappa(e) = 1$ if $e$ is an edge between $B_{ST}$ and $T$ and $\kappa(e) = -1$ if $e$ is an edge between $B_{ST}$ and $S$.

**Theorem 4.4.** $\Sigma = \{(z,w) \in (\mathbb{C}^*)^2 : \det (zI + \Pi(w)) = 0\}$ is the spectral curve.

**Proof.** The Kasteleyn matrix $K(z,w)$ of $\Gamma_{ST}$ has the block matrix form

$$ K(z,w) = \begin{bmatrix} B(\Gamma_A) & B_{ST} \\ K_A(w) & zI \end{bmatrix} \begin{bmatrix} -I \\ zI \end{bmatrix} S. $$

So we have (with $B_S, K_4$ as in (19))

$$ K(z,w)/K_4 = \begin{bmatrix} B_S & B_{ST} \\ I & -I \end{bmatrix} \begin{bmatrix} \Pi(w) \\ zI \end{bmatrix} S. $$

By Theorem A.1 we get $\det K(z,w) = \det K_4 \det (zI + \Pi(w))$. \qed
Figure 7: Elementary transformations allowed in TCD maps: spider move (left) and resplit (right).

Example 4.5. Consider again $\Gamma_2$ for which we have

$$\Pi(w) = \frac{1}{-cg + bfw} \begin{bmatrix} ch + bw \ (ac + bd)w \\ eg + fh \ dg + afw \end{bmatrix}$$

from (21). We have

$$\det (zI + \Pi(w)) = \frac{1}{-cg + bfw} (aew + afwz + bewz + bfwz^2 - cgz^2 + chz + dgz - dh),$$

which agrees with (18).

5 TCD maps on cylinders

5.1 TCD maps

We now describe the cokernel of $K$ from a projective point of view in terms of triple crossing diagram maps, which we abbreviate to TCD maps. Let $\Gamma$ be an arbitrary bipartite graph (not necessarily embedded on a torus) with $|W| > |B|$. Assume that the black vertices of $\Gamma$ are all trivalent, which we can always do using split and join moves. A TCD map is a collection of points $(P_w)_{w \in W}$ such that for each $b \in B$, the three points $P_w$ for $w$ incident to $b$ are distinct and are all contained in a line.

Given a generic weight $w_t$ on $\Gamma$, we obtain a TCD map as follows: consider the exact sequence

$$0 \to \mathbb{C}^B \xrightarrow{K} \mathbb{C}^W \to \text{coker } K \to 0,$$

where $\text{coker } K$ is $(|W| - |B|)$-dimensional. Let $v_w \in \text{coker } K$ be the image of $e_w$. Then the projectivizations $P_w$ of the vectors $v_w$ define a TCD map. Clearly the definition is invariant under gauge equivalence. On the other hand, given a TCD map, we recover the edge-weights modulo gauge transformations from the equations of the lines associated to the black vertices.

Remark. Note that the cokernel is only defined up to isomorphism. Different choices for a representative of the isomorphism class of the cokernel give different TCD maps related by projective transformations.
The advantage of working with $\Gamma$ with trivalent black vertices is that we can keep track of both the geometric dynamics and the invariants while performing local moves. For TCD maps there are only two allowed elementary transformations, the spider move and the resplit, see Figure 7.

In a generic situation, the points associated to white vertices after one of these two moves are determined by the combinatorics. Indeed, no points change when performing the spider move and the new point appearing in the resplit is determined as the intersection of the two lines represented by the two black vertices. It is a straightforward calculation to verify that the edge-weights of $\Gamma$ are compatible with the geometric constraints. In $\mathbb{CP}^1$ however, there is no incidence geometry. In this case, we define the new white vertex in the resplit such that the edge-weights of $\Gamma$ are recovered as multi-ratios as stated in the following Lemma.

Lemma 5.1 ([AGPR19] Proposition 2.6). For a loop $L = w_1 \to b_1 \to w_2 \to b_2 \to \cdots \to w_n \to b_n \to w_1$, let $w'_i$ denote the third white vertex incident to $b_i$ that is not in $\{w_i, w_{i+1}\}$. Then we have

$$[\text{wt}](L) = [k](L)^{-1} \text{mr}(P_{w_1}, P_{w'_1}, P_{w_2}, P_{w'_2}, \ldots, P_{w_n}, P_{w'_n}).$$

Moreover, we make the following observation. Assume the white vertices are labeled as in Figure 7. Then

$$\text{mr}(P_{w_1}, P_w, P_{w_2}, P_{w_3}, P_{w'_4}) = -1$$

holds. Note that this equation has a high degree of symmetry, it also holds if we swap $w \leftrightarrow w'$ or $w_1 \leftrightarrow w_3$ or $w_2 \leftrightarrow w_4$.

5.2 TCD map on $\hat{\Gamma}\hat{\Lambda}$ from $\Gamma$

Suppose $\Gamma\hat{\Lambda}$ is a graph in $\hat{\Lambda}$ obtained from a graph $\Gamma$ in $\hat{T}$ as in Section 4.1. We assume further that there is a dimer cover $M_1$ such that $\partial M_1 = T$, or equivalently that the matrix $\Pi$ in (20) is invertible.

Let $\hat{\Lambda} := H_1(T, \mathbb{R})/\mathbb{Z}[\gamma_w]$ denote the infinite cylinder covering $\Lambda$. Note that $\hat{\Lambda} = \bigcup_{k \in \mathbb{Z}} \Lambda + k[\gamma_w]$, that is $\hat{\Lambda}$ is obtained by gluing together infinitely many copies of $\Lambda$. Let

$$\Gamma\hat{\Lambda} = (B(\Gamma\hat{\Lambda}) \cup W(\Gamma\hat{\Lambda}), E(\Gamma\hat{\Lambda}))$$

(23)

denote the preimage of $\Gamma$ under the covering map $\hat{\Lambda} \to \Lambda$. Fix a white vertex $w \in W(\Gamma\hat{\Lambda})$ and choose a large enough $m$ so that $w$ is in $\Lambda_m := \bigcup_{k \in [-m, m] \cap \mathbb{Z}} (\Lambda + k[\gamma_w]) \subset \hat{\Lambda}$. Let $\Gamma\Lambda_m := \Gamma\hat{\Lambda} \cap \Lambda_m$.

Lemma 5.2. We have $\text{coker } K_{\Lambda_m} \cong \text{coker } K_{\Lambda} \cong \mathbb{C}^{\lvert W \lvert - \lvert B \lvert}$ for all $m \geq 0$. Moreover with these identifications, the image of $e_w$ in $\mathbb{C}^{\lvert W \lvert - \lvert B \lvert}$ under the cokernel map of $K_{\Lambda_m}$ is independent of $m$, where $e_w$ is the unit basis vector corresponding to $w$ in $\mathbb{C}^{\lvert W \lvert (\Gamma_{\Lambda_m})}$.

Proof. Suppose $m > m'$. $K_{\Lambda_m}$ has the block form

$$K_{\Lambda_m} = \begin{bmatrix} B(\Gamma_{\Lambda_m}) & B(\Gamma_{\Lambda_m}) \setminus B(\Gamma_{\Lambda_m}) \\ K_{\Lambda_m} & 0 \end{bmatrix} \begin{bmatrix} * \\ K' \end{bmatrix} \begin{bmatrix} W(\Gamma_{\Lambda_m}) \\ W(\Gamma_{\Lambda_m}) \setminus W(\Gamma_{\Lambda_m}) \end{bmatrix},$$

where
where $K'$ is invertible by existence of $M_0$ and $M_1$, and Theorem 1.1. Therefore $K_{Km} = K_{Km'}$, and so the second statement follows from Theorem A.2. By Theorem A.2 with $m' = 0$ we get \( \coker K_{Km} \cong \coker K_k \cong \mathbb{C}^{W - |B|} \) for all $m \geq 0$.

We define a TCD map \( P : W(\Gamma_k) \to \mathbb{C}P^{W(\Gamma_k) - |B(\Gamma_k)| - 1} \) as follows: For \( w \in W(\Gamma_k) \), we choose $m$ sufficiently large so that \( w \in W(\Gamma_{Km}) \). Let $v_w$ denote the image of $e_w$ in $\mathbb{C}P^{W(\Gamma_k) - |B(\Gamma_k)|}$ as in Lemma 5.2 and define \( P_w \in \mathbb{C}P^{W(\Gamma_k) - |B(\Gamma_k)| - 1} \) to be the projectivization of $v_w$. Lemma 5.2 guarantees that the definition is independent of the choice of $m$.

### 5.3 Monodromy of a TCD map on $\Gamma_k$

A pair \( (P, M) \) where \( P : W(\Gamma_k) \to \mathbb{C}P^{W(\Gamma_k) - |B(\Gamma_k)| - 1} \) is a TCD map and \( M \in \operatorname{PGL}_{W(\Gamma_k) - |B(\Gamma_k)|} \) is called a twisted TCD map. The monodromy of a twisted TCD map $P$ is the Schur complement of $K_k$, by Theorem A.2 we have

\[
\begin{bmatrix}
  v_{w_1 + \gamma_z} & \cdots & v_{w_n + \gamma_z} & v_{w_1} & \cdots & v_{w_n}
\end{bmatrix}
\begin{bmatrix}
  I \\
  \Pi
\end{bmatrix} = 0,
\]

where $v_{w_i}$ is the standard basis vector $e_i$. From this, we get $v_{w_i + \gamma_z} = -\Pi v_{w_i}$. The same argument applied to the translated graph $\Gamma_{k+z}$ gives $v_{w_i + (k+1)\gamma_z} = -\Pi v_{w_i + k\gamma_z}$. This implies $v_{w_i + k\gamma_z} = (-\Pi)^k v_{w_i}$ for all $k \in \mathbb{Z}$. For $w \in W(\Gamma_k)$, since \{\( v_{w_i} \)\} is a basis, there exists $a_k$ such that $v_w = \sum_{i=1}^n a_i v_{w_i}$. Then we have

\[
(-\Pi)^k v_w = \sum_{i=1}^n a_i (-\Pi)^k v_{w_i} = \sum_{i=1}^n a_i v_{w_i + k\gamma_z} = v_{w + k\gamma_z},
\]

where the last equality follows from $K_k = K_{k+z}$. Any white $w' \in W(\Gamma_k)$ is of the form $w + m\gamma_z$ for some $w \in W(\Gamma_k)$. Then $w' + \gamma_z = w + (m + 1)\gamma_z$, so that we have

\[
v_{w'} = (-\Pi)^m v_w, \quad v_{w' + \gamma_z} = (-\Pi)^{m+1} v_w,
\]

and therefore $v_{w' + \gamma_z} = -\Pi v_{w'}$. Projectivizing, we get the statement of the proposition. \[ \square \]
6 Twisted TCD maps from $U_n$ for $n$ even

For $n$ even, recall the graph $\Gamma_n$ from Example 3.1 and let $N$ denote its Newton polygon computed in Example 3.2. Suppose the faces and zig-zag paths of $\Gamma_n$ are labeled as in Figure 2 and Example 3.2 respectively. The set $\{X_1, \ldots, X_n, Y_1, \ldots, Y_n, \chi_{[\xi_1]}, \chi_{[\zeta_1]}\}$ is a set of generators for $\mathcal{O}_{\mathcal{L}_{\Gamma_n}}$ and the only relation among them is $\prod_{i=1}^n X_i Y_i = 1$.

Let $X_{N,\vec{\alpha}}$ (resp. $\mathcal{L}_{\Gamma_n,\vec{\alpha}}$) denote the subvariety of $X_N$ (resp. $\mathcal{L}_{\Gamma_n}$) where

\begin{align}
\chi_{[\zeta_2i-1]} &= 1 - \alpha_{2i-1}, \\
\chi_{[\zeta_{2i}]} &= \frac{1}{1 - \alpha_{2i}}
\end{align}

for all $i \in \{1, 2, \ldots, n\}$. Recall from Section 2 that $U_n \cong (\mathbb{C} \setminus \{0, -1\})^n$.

**Definition 6.1.** We define a rational map

$$\pi_{\vec{\alpha}} : X_{N,\vec{\alpha}} \supset \mathcal{L}_{\Gamma_n,\vec{\alpha}} \to (\mathbb{C} \setminus \{0, -1\})^n$$

such that

$$\pi_{\vec{\alpha}}^* u_i = Y_i,$$ 

for all $i \in \{1, 2, \ldots, n\}$.

**Lemma 6.2.** We have

$$\pi_{\vec{\alpha}}^* v_i = X_i$$

for all $i \in \{1, 2, \ldots, n\}$.

**Proof.** It follows from

$$X_i Y_i = \begin{cases} 
\chi_{[\zeta_i]} \chi_{[\xi_{i-1}]} & \text{if } i \text{ is odd;} \\
\frac{1}{\chi_{[\zeta_i]} \chi_{[\xi_{i-1}]} \zeta_i} & \text{if } i \text{ is even,}
\end{cases}$$

and the equations (24), (25) and (10)).

Next, we check that:

**Lemma 6.3.** $\pi_{\vec{\alpha}}$ is Poisson.

**Proof.** $Y_1, Y_2, \ldots, Y_n$ and $\chi_{[\xi_1]}$ are coordinates on $X_{N,\vec{\alpha}}$. The only nonzero Poisson brackets on $X_{N,\vec{\alpha}}$ in these coordinates are

$$\{Y_i, Y_{i+1}\} = Y_i Y_{i+1}, \quad i = 1, 2, \ldots, n.$$  

(28)

We compute that

$$\pi_{\vec{\alpha}}^* \{Y_i, Y_{i+1}\} = \pi_{\vec{\alpha}}^* (Y_i Y_{i+1}) = u_i u_{i+1} = \{\pi_{\vec{\alpha}}^* Y_i, \pi_{\vec{\alpha}}^* Y_{i+1}\}.$$  

(29)

$\Box$
Figure 8: Edge weights and Kasteleyn signs for the building block graphs $G_i$ (left) as well as $G_{n}^{\text{odd}}$ (right).
6.1 TCD map and the pair of curves

Let \([wt] \in \mathcal{A}_{N,\alpha}\) such that \(u^{-1} \circ \pi_\alpha([wt]) = (p, q, M)\). We choose edge weights representing \([wt]\) and Kasteleyn signs as in Figure 8.

Remark. We have additionally the freedom to choose \(\chi_\xi([wt])\). However this is a Casimir and for our purposes may be absorbed into \(z\) since it changes the Hamiltonians by a multiplicative factor, and does not affect the TCD map.

Note that we have \(|W(\Gamma_{n,\hat{A}})| - |B(\Gamma_{n,\hat{A}})| = 2\). Let \(P : \Gamma_{n,\hat{A}} \to \mathbb{CP}^1\) denote the TCD map associated to \([wt]\). \(\Gamma_{n,\hat{A}}\) is a union of infinitely many copies of the building block graph \(G_i, i \in \mathbb{Z}\).

Lemma 6.4. We have (see Figure 7)

\[
P_{w_i} = \begin{cases} 
q_{2i-1} & \text{if } k = 4i - 3; \\
q_{2i} & \text{if } k = 4i - 1; \\
p_{2i-1} & \text{if } k = 4i - 2; \\
p_{2i} & \text{if } k = 4i,
\end{cases}
\]

up to a projective transformation, for all \(i \in \mathbb{Z}\).

Proof. The discrete curves \(p\) and \(q\) are determined up to projective transformations by the cross-ratios (7) and (8). Using Lemma 5.1, we see from (31) and Lemma 6.2 that the \(P_w\) have the same cross-ratios. \(\square\)

Corollary 6.5. The monodromy matrix of the TCD map \(P\) coincides with the monodromy matrix \(M\) of the pair of discrete curves \(p, q\).

We now compute the monodromy matrix. The Kasteleyn matrix of \(G_i\) is

\[
K_{G_i}(w) = \begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
\frac{\alpha_{2i-1}u_{2i-1}u_{2i}}{\alpha_{2i-1} - \alpha_{2i}w} & \frac{\alpha_{2i-1}u_{2i-1}u_{2i}}{\alpha_{2i-1} - \alpha_{2i}w} & 1 & -u_{2i-1}
\end{bmatrix}
\]

so that

\[
\Pi_{G_i}(w) = \frac{\alpha_{2i-1}}{1 - \alpha_{2i-1}w} \begin{bmatrix}
u_{2i-1}(u_{2i} + (1 - \alpha_{2i})w) & u_{2i-1}(1 + u_{2i}) \\
(1 - \alpha_{2i})w + u_{2i} - u_{2i}(1 - \alpha_{2i-1})w & 1 + u_{2i}(1 - \alpha_{2i-1})w
\end{bmatrix}.
\]

We have \(\det \Pi_{G_i}(w) = \left(\frac{\alpha_{2i-1}}{(1 - \alpha_{2i-1}w)}\right)((1 - \alpha_{2i})w - 1)\alpha_{2i-1}u_{2i-1}u_{2i}.\) By Proposition 4.2, the monodromy matrix is

\[
\Pi(w) = \Pi_{G_1}(w)\Pi_{G_2}(w)\cdots\Pi_{G_{\frac{n}{2}}}(w)
\]

and so we get

\[
\det \Pi(1) = \alpha_{[n]}u_{[n]}, \quad (30)
\]

23
6.2 Hamiltonians

The following lemma is elementary.

Lemma 6.6. Suppose $M$ is a $2 \times 2$ matrix and $P(z) = \det(zI + M)$ is its characteristic polynomial. Then $P(z) = z^2 + \text{tr}Mz + \det M$.

Let $P(z,w)$ denote the characteristic polynomial of $\Gamma_n$, normalized so that it has Newton polygon as in Figure $3$ with the vertex in top right corner corresponding to $z^2w^2$, and such that the coefficient of $z^2w^2$ is $\frac{1}{\alpha_{\text{odd}}} \prod_{i=1}^{\frac{n}{2}} (1 - \alpha_{2i-1})$. To find the normalization explicitly, we know from Theorem $4.4$ and Lemma $6.6$ that $P(z,w)$ is up to normalization equal to $\det(\Pi(z)) = z^2 + \text{tr} \Pi(w)z + \det \Pi(w)$, which is equal to

$$z^2 + \frac{\sum_{i=1}^{\frac{n}{2}} \alpha_{\text{odd}}}{\prod_{i=1}^{\frac{n}{2}} (1 - \alpha_{2i-1})w - 1} \text{tr} \prod_{i=1}^{\frac{n}{2}} \left( \frac{1}{(1 - \alpha_{2i-1})w + u_{2i-1}(1 + \alpha_{2i})} \right) + \text{lower degree terms}.$$  

Let $H_{(1,k)}$ denote the coefficient of $zw^k$ in $P(z,w)$ for $k = 0, \ldots, \frac{n}{2}$, so that when $k \in \{1,2,\ldots,\frac{n}{2} - 1\}$, they are the Hamiltonians of the dimer integrable system. Then we have

$$\sum_{k=0}^{\frac{n}{2}} H_{(1,k)}w^k = \frac{\sum_{i=1}^{\frac{n}{2}} (1 - \alpha_{2i-1})w - 1}{\alpha_{\text{odd}}} \text{tr} \Pi(w)$$

$$= \text{tr} \prod_{i=1}^{\frac{n}{2}} \left[ \frac{u_{2i-1}(u_{2i} + (1 - \alpha_{2i})w)}{(1 - \alpha_{2i})w + u_{2i}(1 - \alpha_{2i-1})w} \right].$$

Make the substitution $\beta_i = 1 - \alpha_i$ and consider the above expression as a polynomial in $\beta_1, \beta_2, \ldots, \beta_n$. Since each $(1-\alpha_i)$ inside the matrices appears with a $w_i$, the homogeneous component of degree $k$ in $\beta_1, \beta_2, \ldots, \beta_n$ is $H_{(1,k)}w^k$.

The main result of this section is the following simple procedure for converting between the AFIT Hamiltonians [AFIT20] and the dimer Hamiltonians.

Theorem 6.7. The homogeneous degree $k$ component of $\sum_{k=0}^{\frac{n}{2}} H_{(1,k)}$ as a polynomial in the variables $\alpha_1, \alpha_2, \ldots, \alpha_n$ is, up to a sign, equal to $\sqrt{\prod_{i=1}^{\frac{n}{2}} \alpha_{\alpha_i}} \pi_{\alpha} \circ \Lambda_{\alpha}^{\alpha} \left( \frac{F_{\alpha}}{\sqrt{\prod_{i=1}^{\frac{n}{2}} \alpha_{\alpha_i}}} \right)$. For $k \in \{1,2,\ldots,\frac{n}{2} - 1\}$, these are AFIT Hamiltonians since $\sqrt{\prod_{i=1}^{\frac{n}{2}} \alpha_{\alpha_i}}$ is a Casimir. The homogeneous degree $k$ component of $\sum_{k=0}^{\frac{n}{2}} H_{(1,k)}$ as a polynomial in $1 - \alpha_1, 1 - \alpha_2, \ldots, 1 - \alpha_n$ is the dimer Hamiltonian $H_{(1,k)}$.

Proof. By Corollary $6.5$, $\Pi(1)$ is conjugated to $\pi_{\alpha} \circ \Lambda_{\alpha}^{\alpha} M$ in PGL$_2$. Since $\frac{1}{\det \Pi(1)} \text{tr}^2 M$ is a PGL$_2$-conjugacy invariant, we have

$$\pi_{\alpha} \circ \Lambda_{\alpha}^{\alpha} \left( \frac{1}{\sqrt{\det \Pi(1)}} \text{tr} M \right) = \pm \frac{1}{\sqrt{\det \Pi(1)}} \text{tr} \Pi(1).$$
Using Theorem 2.3 and (30), we get
\[ \sqrt{Y_{[n]}^{α_{[n]}}} \sum_{k=0}^{\frac{n}{2}} (-1)^k \pi^*_{\alpha} \circ \Lambda^*_{\alpha} \left( \frac{F_k(c)}{\sqrt{c_{[n]}}} \right) = \pm \sum_{k=0}^{\frac{n}{2}} H_{(1,k)}. \]

Note that the left side is a polynomial in \( α_i \) for all \( i \). We label the zig-zag paths as follows: \( \alpha_k \), \( n \) odd, let \( \Gamma \) denote the monodromy matrix of \( \Gamma \). We have
\[ \det(\Pi(1)) = \alpha_n u_n. \]

7 Odd \( n \)

For \( n \) odd, let \( \Gamma_n \) be obtained by gluing the graphs \( G_1 G_2 \cdots G_{\frac{n-2}{2}} G_{\frac{n+1}{2}} G_{\frac{n+3}{2}} \) from left to right and identifying \( w_{2n+1} \) with \( w_1 \) and \( w_{2n+2} \) with \( w_2 \). The Newton polygon of \( \Gamma_n \) is (see Figure 3)
\[ \text{Convex-hull} \left\{ (0,0), (2,0), \left( 0, \frac{n-1}{2} \right), \left( 2, \frac{n+1}{2} \right) \right\}. \]

We label the zig-zag paths as follows:
\[ \begin{align*}
\xi_1 &= w_1, b_1, w_3, b_3, \ldots, w_{2n-1}, b_{2n}, w_1, \quad [\xi_1] = (1,0), \\
\xi_2 &= w_2, b_2, w_4, b_4, \ldots, w_{2n}, b_{2n-1}, w_2, \quad [\xi_2] = (1,0), \\
\sigma &= w_1, b_{2n-1}, w_{2n}, b_{2n-2}, \ldots, w_4, b_1, w_1, \quad [\sigma] = (-2,-1), \\
\zeta_{2i-1} &= w_{4i-1}, b_{4i-3}, w_{4i}, b_{4i-2}, w_{4i-1}, \quad [\zeta_{2i-1}] = (0,1), \\
\zeta_{2i} &= w_{4i-1}, b_{4i}, w_{4i}, b_{4i-2}, w_{4i-1}, \quad [\zeta_{2i}] = (0,-1), \\
\zeta_n &= w_{2n+1}, b_{2n}, w_{2n+2}, b_{2n-1}, \quad [\zeta_{2i}] = (0,1),
\end{align*} \]

where \( i \in \{1,2,\ldots,\frac{n-1}{2}\} \).

Let \( N \) denote the Newton polygon of \( \Gamma_n \). We define a rational map \( \pi_{\vec{\alpha}} : X_{N,\vec{\alpha}} \supset \mathcal{L}_{\gamma_{n,\vec{\alpha}}} \to (\mathbb{C} \setminus \{0,-1\})^n \):
\[ \pi^*_{\alpha} u_i = Y_i, \quad (31) \]

for all \( i \in \{1,2,\ldots,n\} \), which is checked to be Poisson as in the even case. We have
\[ \begin{align*}
\Pi_{G_{\text{odd}}} (w) &= \frac{\alpha_n}{(1-\alpha_n)w-1} \begin{bmatrix} 1 & (1-\alpha_n)w \\ u_n & u_n \end{bmatrix}, \\
\det \Pi_{G_{\text{odd}}} (w) &= \frac{\alpha_n}{(1-\alpha_n)w-1}(-\alpha_n u_n), \\
\det \Pi_{G_{\text{odd}}} (1) &= \alpha_n u_n.
\end{align*} \]

Let \( \Pi(w) \) denote the monodromy matrix of \( \Gamma_n \). As in the even case, we have \( \det \Pi(1) = \alpha_{[n]} u_{[n]} \).

Let \( P(z,w) \) denote the characteristic polynomial of \( \Gamma_n \) normalized as follows
\[ \det(zI + \Pi(w)) = \frac{\alpha_{\text{odd}}}{\prod_{i \in \text{odd}} ((1-\alpha_{2i})w-1)} P(z,w). \]

25
Figure 9: Insertion of $r_1$ in the fundamental domain.

Figure 10: Beginning of the sequence of local moves that propagates $r$ through $(p,q)$.

Let $H_{(1,k)}$ denote the coefficient of $zw^k$ in $P(z,w)$ for $k = 1, \ldots, \frac{n+1}{2}$. Note that $(1 - \alpha_n)$ appears with a $w$ in (32), so as before $H_{(1,k)}w^k$ is the homogeneous component of degree $k$ in $1 - \alpha_1, 1 - \alpha_2, \ldots, 1 - \alpha_n$. Theorem 6.7 holds verbatim, after making the necessary adjustment of the indices.

**Theorem 7.1.** The homogeneous degree $k$ component of $\sum_{k=0}^{\frac{n}{2}} H_{(1,k)}$ as a polynomial in the variables $\alpha_1, \alpha_2, \ldots, \alpha_n$ is, up to a sign, equal to $\sqrt{Y[n]\alpha[n]^{*}} \Lambda_{\alpha}^{*} \left( \frac{F_0(c)}{\sqrt{c}} \right)$. For $k \in \{1, 2, \ldots, \frac{n-1}{2}\}$, these are AFIT Hamiltonians since $\sqrt{Y[n]\alpha[n]}$ is a Casimir. The homogeneous degree $k$ component of $\sum_{k=0}^{\frac{n}{2}} H_{(1,k)}$ as a polynomial in $1 - \alpha_1, 1 - \alpha_2, \ldots, 1 - \alpha_n$ is the dimer Hamiltonian $H_{(1,k)}$.

### 8 Cross-ratio dynamics via local moves

In this section we show that cross-ratio dynamics, that is the map $\nu_\mathcal{D} : (p,q,M) \mapsto (q,r,M)$ is identified with a certain sequence of local moves on the dimer side. We prepare with an observation on multi-ratios.

**Lemma 8.1.** Assume $p, q, r$ are nondegenerate twisted curves such that $p \neq r$ and both $p$ and $r$ are $\overrightarrow{\alpha}$-related to $q$. Then

\[ \text{mr}(p_i, q_i, r_i, r_{i+1}, q_{i+1}, p_{i+1}) = -1 \] (33)
holds for all \( i \in \mathbb{Z} \).

**Proof.** The Lemma follows directly from the fact that both

\[
\begin{align*}
\text{cr}(p_i, q_i, q_{i+1}, p_{i+1}) &= \text{cr}(q_i, r_i, r_{i+1}, q_{i+1}), \\
\text{mr}(p_i, q_i, r_i, r_{i+1}, q_{i+1}) = -\frac{\text{cr}(p_i, q_i, q_{i+1}, p_{i+1})}{\text{cr}(q_i, r_i, r_{i+1}, q_{i+1})}
\end{align*}
\]

(34) (35)

hold for all \( i \in \mathbb{Z} \).

Now we construct the sequence of moves.

**Theorem 8.2.** Suppose \([\mathbf{wt}] \in \mathcal{X}_{N, \vec{\alpha}}\) is such that \( u^{-1} \circ \pi_{\vec{\alpha}}([\mathbf{wt}]) = (\mathbf{p}, \mathbf{q}, \mathbf{M}) \). Consider the sequence of moves shown in Figures 9, 10, and let \( \mu \) denote the induced birational map of weights. Then the pair of curves \( (\mathbf{q}, \mathbf{r}, \mathbf{M}) \) is \( u^{-1} \circ \pi_{\vec{\alpha}} \circ \mu([\mathbf{wt}]) \). In other words, the following diagram commutes:

\[
\begin{array}{ccc}
\mathcal{X}_{N, \vec{\alpha}} & \xrightarrow{u^{-1} \circ \pi_{\vec{\alpha}}} & \mathcal{U}_n \\
\mu \downarrow & & \downarrow \nu_{\vec{\alpha}} \\
\mathcal{X}_{N, \vec{\alpha}} & \xrightarrow{u^{-1} \circ \pi_{\vec{\alpha}}} & \mathcal{U}_n
\end{array}
\]

**Proof.** By Lemma 6.4, it suffices to trace what happens to the TCD map associated to \([\mathbf{wt}]\) through the sequence of moves. Let us initially assume that we deal with a periodic instead of a twisted curve. Assume \( n \) is even. We proceed in four steps:

1. First, we need to insert \( r_1 \) into the graph, see Figure 9 for an illustration. To do this, we begin by splitting \( p_1 \) into two copies of \( p_1 \) and a new black vertex \( b \). Then we add a bigon with vertices \( b, q_1 \), such that the bigon is inside the face also bounded by \( p_2 \) and \( p_n \). Finally we split \( b \) into two new black vertices of degree three while also generating the new white vertex corresponding to \( r_1 \).

2. We apply a sequence of spider moves and replots to propagate \( r_1 \) through the graph, see Figure 10. To replace both \( p_{2i-1} \) and \( p_{2i} \) with \( r_{2i} \) and \( r_{2i+1} \) we need to apply a replot, then two spider moves and then a replot again. Each time we apply a replot, we check that the points before and after are related as in Lemma 8.1. This ensures that we are not changing the face-weights of \( \Gamma \), as discussed in Section 5.1. We apply these moves until we have replaced \( p_n \) with a new copy of \( r_1 \).

3. After the moves of step 2 there is still one copy of \( p_1 \) left in the graph. The situation at \( p_1 \) looks like in the rightmost graph in Figure 9 except that the roles of \( p \) and \( r \) are interchanged. We can therefore absorb \( p_1 \) again by doing step 1 backwards. Here, it is essential that the two copies of \( r_1 \) coincide with each other in \( \mathbb{C}P^1 \). After a rescaling at \( r_1 \), we can assume the lifts in \( \mathbb{C}^2 \) coincide as well. This ensures that the corresponding edge-weights in the contraction and the removal of the bigon agree up to a common factor. This common factor can be set to \(-1\) by a rescaling at one of the involved black vertices.

4. Finally, we translate \( \Gamma_n \) by \( \frac{1}{2} \gamma_{\mathbf{w}} \) to interchange \( q \) and \( r \).
If $n$ is not even, the procedure is almost identical. We also split $p_1$, but we insert the bigon in the face also bounded by $p_2$ and $q_n$. Propagation and absorption of $p_1$ works as in the even case, see Figure 11 for an illustration. This concludes the proof in the periodic case. In the twisted case, we apply the same sequence of moves in the fundamental domain. Instead of inserting $r_1$, we simultaneously insert $r_{1+m\gamma}$ for all $m \in \mathbb{Z}$. We proceed analogously in Step 3 where we contract pairs of $p_{1+m\gamma}$ for all $m \in \mathbb{Z}$.

Since the weights of the two edges of a bigon sum to zero, the weight of any dimer cover that uses one of the edges of the bigon is canceled by the weight of the dimer cover that uses the other edge. Therefore the dimer Hamiltonians are unchanged on inserting a bigon. Since the dimer Hamiltonians are also preserved by the elementary transformations ([GK13, Theorem 4.7]), we obtain:

**Corollary 8.3.** The dimer Hamiltonians are invariant under cross-ratio dynamics.

**Appendix A  Schur complement**

Suppose $M = \begin{bmatrix} A & B \\ C & D \end{bmatrix}$ is a $(p+q) \times (r+q)$ block matrix with $D$ an invertible $q \times q$ matrix. Let $V := \text{coker } M$. Let $e_i$ denote the $i$th basis column vector, and let $v_i \in V$ denote the image of $e_i$ under the cokernel map. Let $M/D := A - BD^{-1}C$ denote the Schur complement.
Theorem A.1 (Schur determinant formula [Sch17]). If $M$ is a square matrix ($p = r$), then we have
\[ \det(M) = \det(D)\det(M/D). \]

Theorem A.2. $\text{coker } M/D \cong \text{coker } M$, and under this identification the cokernel map of $M/D$ is $e_i \mapsto v_i$ for $i = 1, \ldots, p$.

Proof. After a change of basis, $M$ takes the block diagonal form
\[ \begin{bmatrix} M/D & 0 \\ 0 & D \end{bmatrix}. \]

Since $D$ is invertible, we have $\text{coker } D = 0$. Therefore we have $\text{coker } M \cong \text{coker } M/D \oplus \text{coker } D \cong \text{coker } M/D$. Under the change of basis
\[ \begin{bmatrix} I & BD^{-1} \\ 0 & I \end{bmatrix} \]of $\mathbb{C}^{p+q}$, we have
\[ e_i \mapsto \begin{bmatrix} I & BD^{-1} \\ 0 & I \end{bmatrix}^{-1} e_i = e_i \text{ for } i = 1, 2, \ldots, p, \]
from which we see that the cokernel map of $M/D$, when we identify $\text{coker } M/D$ with $\text{coker } M = V$, is given by $e_i \mapsto v_i$. \qed
