

## Notes on using MATLAB

MATLAB is an interactive program for numerical methods, with graphing capability. These notes describe some useful functions and syntax. The following sites have more extensive tutorials:

The command for starting MATLAB depends on your system configuration (you can often start MATLAB on UNIX systems by typing **matlab**). To obtain help from within MATLAB, type **help**; this provides a list of available functions. Supply the function name for information about a particular item (e.g. **help plot**). For demonstration of a few commands, type **demo**. To terminate a MATLAB session, type **quit**.

Formats for printing numbers.

**format short**    3.1416

**format short e** 3.1416e+00

**format long**    3.14159265358979

**format long e** 3.141592653589793e+00

There is only one data type in MATLAB, complex matrices. Vectors and scalars are special cases. Matrices can be created as follows, **A = [1, 1, 1, 1; 1, 2, 3, 4]**. This creates a  $2 \times 4$  matrix A whose first row is (1,1,1,1) and whose second row is (1,2,3,4). The dimensions of a matrix A can be found by typing **size A**.

To create a vector, type **x=[1,2,3,4]**. The system responds with:

```
x =  
  
    1    2    3    4
```

The commas are optional, **x=[1 2 3 4]** gives the same result. If an assignment statement ends with a semicolon, then the result is not displayed. Thus if you type **x=[1 2 3 4];**, nothing will be displayed. You can then type **x** to display the vector. The length of a vector **x** is obtained from **length(x)**. Indices for vectors and matrices must be positive integers. Thus, **A(1.5,2)** and **x(0)** are not allowed. There is a special syntax for creating a vector whose components differ by a fixed increment. Thus, **x=[0 .2 .4 .6 .8 1]** can be created by typing **x=0:.2:1**.

Built-in functions.

**pi**                    3.1415....

**zeros(3,3)**           3×3 matrix of zeros

**eye(5)**                5×5 identity matrix

**ones(10)**             vector of length 10 with all entries =1

**abs(x)**                absolute value

**sqrt(x)**              square root, e.g. **i=sqrt(-1)**

**real(z), imag(z)**    real, imaginary parts of a complex number

<b>conj(z)</b>	complex conjugate
<b>atan2(y,x)</b>	polar angle of the complex number $x + iy$
<b>sin(x), cos(x)</b>	trig functions
<b>sinh(x), cosh(x)</b>	hyperbolic functions
<b>exp(x)</b>	exponential function
<b>log(x)</b>	natural logarithm
<b>gamma(n)</b>	gamma function = $(n-1)!$
<b>bessel (a,x)</b>	bessel function of order a at x

Example of a loop.

```
for i = 1:4
    x(i) = i;
end
```

Example of a conditional.

```
if a==0;
    x = a+1;
elseif a < 0;
    x = a-1;
else;
    x = a+1;
end
```

Plotting.

<b>plot(x,y)</b>	linear plot, uses defaults limits, <b>x</b> and <b>y</b> are vectors
<b>grid</b>	draw grid lines on graphics screen
<b>title('text')</b>	prints a title for the plot
<b>xlabel('text')</b>	prints a label for the x-axis
<b>ylabel('text')</b>	prints a label for the y-axis
<b>axis([0, 1, -2, 2])</b>	overrides default limits for plotting
<b>hold on</b>	superimpose all subsequent plots
<b>hold off</b>	turns off a previous hold on
<b>clg</b>	clear graphics screen
<b>mesh</b>	3-d plot; type <b>help mesh</b> for details
<b>contour</b>	contour plot; type <b>help contour</b> for details
<b>subplot</b>	several plots in a window; type <b>help subplot</b> for details

Example. To plot a Gaussian function, type the following lines:

```
x = -3.:.01:3;
y=exp(-x.*x);
plot(x,y)
```

Matrix functions.

<b>x = A\b</b>	gives the solution of $Ax=b$
<b>[l,u] = lu(A)</b>	LU decomposition of A
<b>[v,d] = eig(A)</b>	eigenvalues in d, eigenvectors in v
<b>[u,s,v] = svd(A)</b>	singular value decomposition

<b>chol(A)</b>	Cholesky factorization
<b>inv(A)</b>	inverse of a square matrix
<b>rank(A)</b>	matrix rank
<b>cond(A)</b>	condition number
<b>*</b> , <b>+</b>	matrix product and sum
<b>.*</b> , <b>.+</b>	element by element product and sum
<b>'</b>	transpose, e.g. <b>A'</b>
<b>^</b>	power, e.g. <b>A ^ 2</b>
<b>.^</b>	element by element power, e.g. <b>A.^ 2</b>

m-files.

An m-file is a file that contains a sequence of MATLAB commands. Some m-files are built into MATLAB. A user can create a new m-file using an editor. For example, an m-file called `fourier.m` could be created containing the lines:

```
%
% Plot a trigonometric function.
%
x = 0:.01:1;
y=sin(2*pi*x);
plot(x,y)
```

In this case, typing `fourier` would produce a plot of a sine curve. (Note: `%` in an m-file denotes a comment line.) In order to pass arguments to and from an m-file, the word “function” must be on the first line. For example:

```
function [x,y] = fourier(n,xmax)
%
% Plot a trigonometric function.
%
x=0:.01:xmax;
y=sin(n*pi*x);
plot(x,y)
```

Typing `[x,y] = fourier(2,7);` plots a sine curve. After execution, the vectors `x` and `y` are available for further calculations.

Useful commands.

<b>type dft</b>	lists the contents of the m-file <code>dft.m</code>
<b>save A</b>	stores a matrix in a file called <code>A.mat</code>
<b>save</b>	saves all variables in a file called <code>matlab.mat</code>
<b>load temp</b>	retrieves all the variables from file <code>temp.mat</code>
<b>print</b>	prints the current graphics window
