CB46000

This locus of topsoil is a continuation of the topsoil locus from CB4.6SE, used in '00. The soil was dark brown with many clumps, much plant activity, and sections of large rubble in the NW, NE, and in the central portion at the southern edge of the trench. The locus comes down directly on a locus of topsoil and subsoil, CB46021, which contained a large deposit of mendable pottery.

CB46003

This locus is a continuation of the North Wall of the PHAB, exposed in CB4.6SE in 2000. Running along the northern edge of the trench, only one course of this wall is exposed in this trench, and only the southern face was exposed. The exposed stones are probably the foundation stones of the North Wall, because they extend farther south than the standing portions of the wall extant in other trenches. The wall is composed of small and medium sized rocks, and it appears that the few remaining stones of the drain, CB46020, were incorporated into the wall. The robbing trench CB46022 is directly above and to the south of the wall, above the undisturbed deposit CB46027, which abuts the southern face of the wall. The soil directly on top of the wall was especially hard, particularly in the area around the drain.

CB46019 is an E/W wall located at the southern end of CB4.6 Sw. The wall is robbed out to the foundation level on the western half of wall CB4.6 Sw. The eastern part is preserved enough to tell that piers and rubble construction was used. It is only partially in CB4.6 Sw, running along the southern edge, with the remaining in 3.6 Sw. The length of the wall is about 3.2m and requires meters in length. The width of the wall is 52cm. The eastern part of the wall contained a grinding installation CB7019 and is preserved with 2 courses remaining. It is located under CB46019, CB46023, CB46028, and CB46029.
CB46018

This wall extends along the southern trenchline, halfway into CB3.6. There is a threshold on the eastern edge, and the wall itself appears to have been dismantled in two stages. The first stage turned a portion of this wall into a grinding installation, and the lack of flooring over the western, dismantled portion of the wall suggests that the wall to the west of this installation was preserved, at least to a height above the floor levels. The second stage is a dismantling of the western portion of this wall before the thick plaster floor, CB46023, was placed over it. This locus is below CB46028 and to the west of installation CB46019.

CB46019

This is the grinding installation present in the remaining portion of wall CB46018. Above this is CB46023.1. The grinding installation does not contain a grinding stone, but does have supporting blocks where one was likely placed. This was probably used in the phase before the thick plaster floor, CB46023, was made.

CB46021

This locus is topsoil and subsoil that covers the extent of the exposed trench. The soil was dark brown at the top, with much plant activity, and became light brown. The plant activity continued throughout the subsoil portion of this locus, and there was small to medium sized rubble in the North, and one large ashlarp in the south baulk, removed with the 3.6NW baulk removal. Directly below topsoil locus CB46000, this locus comes down onto a thick plaster floor, CB46023, and passes over both the robbing trench of the North Wall, CB46022, and the robbing trench of CB46001, CB46025. Although part of this locus is topsoil, the units in this locus contain a particularly nice, dense pottery assemblage. This assemblage is mostly Hellenistic, but has an LDM throughout of Ras-al-Fukra, and was at least partially in a plow zone. It is not clear whether or not this deposit of pottery represents the original contents of this area or if it was moved here from elsewhere, possibly the large pit in CB37SE.

CB46022

This locus is a robbing trench of the North wall of the PHAB, CB46001. The subsoil locus that contained the Hellenistic pottery assemblage, CB46021, came directly down onto this robbing trench and contained some of the rubble associated with it. This robbing trench cut through the large plaster floor, CB46023, and came down upon the drain, CB46XX. The robbing trench is above an undisturbed deposit, CB46027, and touches the robbing trench of wall CB46002, which is CB46025. The soil in this deposit was light brown to grayish brown and contained many small and medium sized rocks. Though the LDM is Gamla cookware, it is likely that this wall, like many others at this site, was robbed in the Roman period.

CB46023

This locus is a thick plaster floor that covered the trench, except for the areas of the robbing trenches, CB46022 and CB46025, which touch this locus. The plaster in this floor, while thick, is not as well preserved as the floor in the storage room of CB4.7, which is at approximately the same elevation. This shows that the plaster floor of 4.6 was likely exposed for a longer period of time. This floor is under the subsoil locus, CB46021, and over CB46023.1, floor CB46026, wall CB46018, and the grinding installation within that wall, CB46019. It touches wall CB36038, the southern wall of the corridor. The plaster floor was thickest in the southern portion of the trench, over the wall and grinding installation, 13.5cm. Its thinnest point was in the North, south of the robbing trench of the North wall of the PHAB, where it reached just 3cm. It is possible that this was the original edge of this floor and that there was an installation just north of it, but there are no remnants of this now. The LDM of this floor and the material below it, CFN, suggest that this floor was created and in use during the last phase of the Building Hellenistic.

CB46023.1

This is the sealed deposit under the thick plaster floor, CB46023. It is below only CB46023 and touches the robbing trenches, CB46022 and CB46025. This deposit includes material both north and south of the wall and grinding installation, CB46018 and CB46019, and is also above the disturbed soil in the threshold, CB46031 and the fill over the West side of wall CB46018, which is CB46028. It also touches the dirt, pebble, and plaster floor that was preserved only in the north of the trench, CB46026, and likely contains material that was once part of that floor. The dirt, pebble, and plaster floor was likely a working surface for the creation of CB46023, and the ceramic assemblages of this working surface and CB46023.I are very similar, especially the presence of deliberately chipped amphorae fragments. This locus contains three large rocks, including one possible stylobate block, which were likely placed purposefully before the construction of the thick plaster floor of CB46023.

CB46024

This locus is a circular pit of very soft soil and some rubble that abuts the northern face and foundation stones of wall CB36038. The pit extends below the level of the foundation stones of CB36038 and is below only CB46023.1. It is unclear at what point this pit was dug, but it was present before the fill below the plaster floor was deposited. It is possible that this pit represents the remnants of some sort of oven or cooking area, given the soft, silty texture of the soil and the burnt quality of some of the pottery within it.

CB46026.1

This locus is the .1 of the dirt, pebble, and plaster floor that was probably a working surface created for the thick plaster floor, CB46023. This is directly below CB46026 and above CB46029, a lower crushed limestone floor to the north of wall/grinding installation CB46018/19. To the south, it abuts the wall/grinding installation CB46018/19. The soil in this locus is semi-compact, grayish brown and contains many small and medium rocks. The LDM for this locus is Local Fine.

CB46027

This locus is a non-sealed deposit directly under the northern robbing trench, CB46022, north of the line of the preserved plaster floor CB46023. The LDM of Local Fine and Hellenistic Black Glaze combined with the similar elevation of CB46026.1 suggests that this was probably also under floor CB46026 before the robbing trench of the North Wall of the PHAB, CB46022, cut through the floor. The soil is semi-compact, grayish brown, slightly crumbly, and contained some small rocks.

CB46028

This locus is the deposit of soil over the dismantled western portion of wall CB46018. Directly under CB46023.1, it is likely that this soil was deposited as a fill when the wall was dismantled before the construction of the plaster floor, CB46023. With an LDM of Local Fine, it is unclear where the soil in this fill and the fill that makes up CB46023.1 came from. The soil in this fill was soft, medium brown, non-compact, and contained some small and medium rocks.

CB46029

This locus is the lower crushed limestone floor directly under CB46026.1 and over CB46029.1. Only a 1.5 meter strip of this floor, running E-W was exposed and excavated due to time constraints. The floor extends to the northern face of wall CB46018 and runs over the threshold of this wall that is in the eastern portion of the trench. The section of flooring that runs over the threshold is a separate locus, CB46031. Although the limestone floor to the north of the threshold is contiguous with that in the threshold, the likely action of removing the threshold block during the wall dismantling embedded material later than that present to the north of the threshold. The floor itself is made from crushed limestone, soil, and small rocks, which were likely placed as a subfloor. The LDM of this floor is Local Fine.

CB46029.1

This locus is the .1 of the lower crushed limestone floor, CB46029. We were only able to excavate a sealed area of approximately 1.5x1.5 meters along the center of the east portion of the trench due to time constraints, so the pottery sample was rather small. The LDM is a combination of a semi-fine folded lamp, a neckless cookpot, and Spatter. The soil in this locus is medium brown, soft, with some small rocks. It is directly above CB46031, the lowest crush limestone and pebble floor that this locus exposed, but left unexcavated. CB46029.1 abuts wall CB46018 to the south.

CB46031

This locus is the fill inside the threshold of wall CB46018. Directly under CB46023.1, this fill was probably deposited when the stylobate block was removed from the threshold and used to level out the area before creating the thick plaster floor, CB46023. It was probably this action that left the LDM of Coastal Fine North, which was consistently the LDM for the units that made up the loci of CB46023 and CB46023.1. The soil in this locus was medium brown, semi-compact, and contained some small and medium rocks, as well as a grinding stone.
