Complex Systems 535/Physics 508: Network Theory

Fall 2014

Time: Monday and Wednesday, 1–2:30pm
Room: 2218 School of Education building

Instructor: Mark Newman
Office: 322 West Hall
Office hours: Tuesdays 1:30–3:30pm
Email: mejn@umich.edu

Web site:

Everything on this information sheet, and more, can be found on the course web site:

http://www.umich.edu/~mejn/courses/2014/cscs535

Description:

This course will introduce and develop the mathematical theory of networks, particularly social and technological networks, with applications to network-driven phenomena in the Internet, network resilience, search engines, epidemiology, and many other areas. Topics to be covered will include experimental studies of social, technological, and biological networks; methods and computer algorithms for the analysis and interpretation of network data; graph theory; models of networks including random graphs and preferential attachment models; spectral methods and random matrix theory; maximum likelihood methods; percolation theory; network search.

Requirements:

Students should have studied calculus and linear algebra before taking the course, and should in particular be comfortable with the solution of linear differential equations and with the calculation and properties of eigenvalues and eigenvectors of matrices. In addition, a moderate portion of the course, perhaps two weeks, will deal with computer methods for studying networks. Some experience with computer programming will be a great help in understanding this part of the course.

Coursework:

There will be weekly graded problem sets, consisting both of theory questions and of problems demonstrating applications of theory to example networks. There will be three midterm exams but no final. Grade will be 25% on the homeworks and 25% on each of the midterms.

There will be reading assignments for each lecture. The assignments are listed on the web site. Students are expected to do the reading for each lecture in a timely manner.
Textbook (required):

Other books and reviews:

I know of two other general textbooks in this area. Both are short and don’t contain as much detail as we’ll cover in the course, but they may be of interest if you want a second opinion on something:

There are a number of review articles that cover parts of the syllabus:

There are various specialized books that cover parts of the syllabus in greater depth. None of these books is required, but if you want to look at them I’d recommend for graph theory either West or Wilson, and for social network analysis either Scott or Wasserman and Faust. The Ahuja et al. book is excellent if you’re interested in the computer programming/algorithms side of things, and the books by Jackson and by Easley and Kleinberg are both good for the economics/collective action angle, which we won’t be discussing much in the course. The books by Watts and by Barabási are pop-science treatments that are non-serious but fun to read.
