This paper has been submitted for consideration for publication in Biometrics
S1. Selection of initial values and tuning parameters

To implement the Algorithm, we need to supply reasonable initial values following four steps.

Step 1. We obtain the initial values \( \gamma^{(0)} \) and \( \beta^{(0)} \) for \( \gamma \) and \( \beta \) by minimizing
\[
\sum_{i=1}^{n} \sum_{j=1}^{n_i} \{ Y_i(t_{ij}) - \gamma' B_n(t_{ij}, X'_i \beta) \}^2,
\]
that ignoring correlations and heterogeneity.

Step 2. Denote \( R_i(t_{ij}) = Y_i(t_{ij}) - \gamma^{(0)' B_n(t_{ij}, X'_i \beta^{(0)})} \). Based on a homogeneous variance model, that is, \( \text{var}(\xi_{ik}) = \rho_k \), we estimate the eigenfunctions \( \phi_k^{(0)}(t) = \eta_k^{(0)' B_n 1(t)} \) by applying the package of \text{fpca} for FPCA to \( R_i(\cdot), i = 1, \ldots, n \).

Step 3. We obtain the initial ridge estimator of \( \zeta^{(0)} \), \( \zeta^{(0)}(0) \), for fixed \( \beta^{(0)}, \gamma^{(0)} \) and \( \phi_k^{(0)} \), by minimizing
\[
-L_n(\pi, \zeta) + \lambda_{ini} \| \zeta \|^2_F \text{ with respect to } \zeta,
\]
which is implemented by iteration solution of \( \zeta \) as the minimizer of \( \frac{1}{2h_{ini}} \| \tilde{\zeta} - \{ \tilde{\zeta} + h_{ini} \tilde{L}(\tilde{\zeta}; \pi) \} \|^2_F + \lambda_{ini} \| \zeta \|^2_F \), with \( \tilde{\zeta} \) being the estimate of \( \zeta \) from the previous step. Then, we obtain \( \alpha^{(0)} \) by applying the package of \text{MAVE}, and obtain \( \theta^{(0)} \) by minimizing \( \sum_{i=1}^{n} \sum_{k=1}^{K_n} \{ \zeta_{ik} - \theta_k^{(0)' B_n 2(X'_i \alpha_k)} \}^2 \).

Step 4. Finally, let \( \Sigma_{ni}^{(0)} = B_n 1(t_i)' \sum_{k=1}^{K_n} \eta_k^{(0)' B_n 2(X'_i \alpha_k^{(0)})} \eta_k^{(0)' B_n 1(t_i)} \). Then, \( \sigma^{2(0)} = \sum_{i=1}^{n} \text{tr}\{ (\Sigma_{ni}^{(0)} - R_i(t_i)R_i(t_i)') \} \).

We move on to detail the selection of the step lengths \( \kappa, h, \nu \), the number of FPCs \( K_n \), and the tuning parameter \( \lambda \). First, following [Beck (2014)], we take small constants for \( \kappa, h, \nu \) to ensure the convergence of the algorithm. Second, as in [James et al. (2000); Happ and Greven (2018)], we choose \( K_n \) by using the proportion of variability explained by each principal component. Particularly, we choose \( K_n \) so that \( \sum_{k=1}^{K_n} \rho_k^{(0)} / \sum_k \rho_k^{(0)} \geq 95\% \), where \( \rho_k^{(0)} \) is the initial value for \( \rho_k \), obtained by applying the package \text{fpca} to \( R_i(\cdot), i = 1, \ldots, n \). We also note, unlike the traditional FPCA, the proposed estimation is less sensitive to the choice of \( K_n \) since we will further select FPCs for each individual using individual-specific penalties.
Third, we select \( \lambda \) by minimizing the generalized cross-validation (GCV) error:

\[
GCV = \frac{\sum_{i=1}^{n} \sum_{j=1}^{n_i} (Y_i(t_{ij}) - \hat{Y}(t_{ij}))^2}{N_0(1 - df/N_0)^2},
\]

where \( N_0 = \sum_{i=1}^{n} n_i \) and \( df = p(1 + K_n) + 2K_nm_{n1} + m_{n1}m_{n2} + 1 \), the number of parameters in model (6) available to estimate \( Y_i(t_{ij}) \). We have confirmed the performance of our tuning procedure via simulations in Section 4.

S2. Supplementary materials in simulation and real data analysis

S2.1 Supplementary results in simulation studies

Example 1. Figures S1 and S2 plot the estimates of \( \phi_k(t) \) and \( \rho_k(u) \), \( k = 1, 2, 3 \), and their 95% pointwise confidence intervals based on 500 bootstrap samples for various settings, where the solid, dashed and dotted lines, respectively, represent the true functions, the average of the estimated functions, and the 95% pointwise confidence bands. It appears that the average of the estimated functions coincides with the truth, with the confidence intervals covering the truth as well. As shown in Figure S3, all of the estimated mean functions overlap with the truth, and the performance improves with increased sample sizes.

[Figure 1 about here.]

[Figure 2 about here.]

[Figure 3 about here.]

Tables S1 show the proposed estimator \( \alpha \) presents smaller biases and variances than SSV for both kinds of distributions.

[Table 1 about here.]

Example 2. Table S2 shows the calculated Type-1 error rates and power levels obtained under significant level 0.05, suggesting that the Type-1 error rate of all parameters is
controlled at approximately 0.05, and the power tends to 1 as the sample size increases.

Example 3. Table S3 presents the biases and empirical standard deviations for the parametric and non-parametric estimates obtained by FRIS and SSV for the SSV data.

Example 4. Table S4 shows the $p$-values for $\beta$ and $\alpha$ by FRIS, which suggest that the mean significantly depends on $X_{i1}$ and $X_{i3}$ and the covariance is associated with $X_{i2}$ under the level of 0.05.

Example 5. We consider a multiple index model satisfying

$$E(Y_i|X_i) = \mu_i(X_i) = \mu(t_i, X_i'\beta_1, X_i'\beta_2), \text{cov}(Y_i|X_i) = \Sigma_i,$$

where $\Sigma_i = \sum_{k=1}^{3} \phi_k(t_i) \rho_k(X_i'\alpha_{k1}, X_i'\alpha_{k2}) \phi_k(t_i) + \sigma^2 I_{n_i}$. $\mu(t, u_1, u_2) = 10t \cdot \{\exp(u_1) + \exp(u_2)\}$ and $\rho_k(u_1, u_2) = 10^{2-k}(u_1u_2)^2 I(u_1u_2 < 0), k = 1, 2, 3$. Set $\beta_1 = (0.6, 0, 0.8), \beta_2 = (1, 0, 0), \alpha_{k1} = (0, 0.8, 0.6), \alpha_{k2} = (0, 1, 0), k = 1, 2, 3$. Other setting is the same as that in Example 1(1). The setting in Example 5 implies that the covariates $(X_{i1}, X_{i3})$ are associated with the mean, and the covariates $(X_{i2}, X_{i3})$ are associated with the covariance of the functional response.

Table S5 summaries the estimates and the $p$-values for $\beta$ and $\alpha$ by FRIS. From the $p$-values, it can be seen that the covariates $X_{i1}$ and $X_{i3}$ have significant contribution to the mean part, and $X_{i2}$ and $X_{i3}$ have significant association with the covariance under the level of 0.05. Hence, the Type I error is well-controlled for the multiple index model by FRIS.
S2.2 Supplementary results in real data analysis

In this section, we present supplementary results to the real data. Figure S4 shows the estimated results of the binary function $\mu(t, u)$ of FRIS and SSV in real data. The two functions are very similar, indicating that our method is relatively accurate.

[Figure 4 about here.]

S3. Proof

S3.1 Notation

Let $\mathbb{P}_n$ be the empirical measure of $\{(Y_i, X_i) : i = 1, 2, \ldots, n\}$, and $\mathbb{P}$ be the probability measure of $(Y, X)$. Define the log-likelihood as

$$l(\pi) = -\frac{1}{2} \log |\Sigma| - \frac{1}{2} (Y - \mu)' \Sigma^{-1} (Y - \mu),$$

where $\mu = \mu(t, X'\beta)$, $\Sigma = \sum_{k=1}^{K_n} \phi_k(t)\rho_k(X'\alpha_k)\phi_k(t)' + \sigma^2 I$. Let $\vartheta = (\beta', \alpha')'$, $\psi = (\sigma^2, \mu, \phi_k, \rho_k)'$ and $\pi = (\vartheta', \psi')$.

Define

$$\mathcal{H}_{r,d} = \left\{ f(\cdot) : \left| \frac{\partial^l f}{\partial x_1^{a_1} \cdots \partial x_d^{a_d}}(x) - \frac{\partial^l f}{\partial y_1^{a_1} \cdots \partial y_d^{a_d}}(y) \right| \leq c \| x - y \|^s, \text{ for any } x, y \in \mathbb{R}^d \right\},$$

for $l \in \mathbb{N}_+, s \in (0, 1]$ with $r = l + s$, for any $a = (a_1, \ldots, a_d) \in \mathbb{N}_+^d$ with $\sum_{j=1}^d a_j = l$, and for a $c > 0$.

Let $h = (1, h_1, h_2, h_3)' \in R \times \mathcal{H}_{r,2} \times \prod_{j=1}^{K_n} \mathcal{H}_{r,1} \times \prod_{j=1}^{K_n} \mathcal{H}_{r,1}$ with $h_2 = (h_{2,1}, \ldots, h_{2,K_n})'$ and $h_3 = (h_{3,1}, \ldots, h_{3,K_n})'$. Let $\tilde{i}_\alpha = (\tilde{i}_{\alpha_1}'(\cdot), \ldots, \tilde{i}_{\alpha_{K_n}}'(\cdot))'$, $\tilde{i}_\varphi[h_2] = (\tilde{i}_{\phi_{h_{2,1}}}[\cdot]'(\cdot), \ldots, \tilde{i}_{\phi_{h_{2,K_n}}}[\cdot]'(\cdot))'$, and $\tilde{i}_{\rho}[h_3] = (\tilde{i}_{\rho_1}[\cdot]'(\cdot), \ldots, \tilde{i}_{\rho_{K_n}}[\cdot]'(\cdot))'$. Define $l_1(\pi) = \partial l(\pi)/\partial \vartheta = (\tilde{i}_\beta, \tilde{i}_\alpha)'$, and $l_2(\pi)[h] = \partial l(\pi)/\partial \psi$.
\[ \frac{\partial l(\vartheta, \psi + sh)}{\partial s} \bigg|_{s=0} = (\hat{l}_\beta, \hat{l}_\alpha, \hat{l}_\varphi, \hat{l}_\rho [h_1], \hat{l}_\rho [h_2], \hat{l}_\rho [h_3])', \]

where

\[
\hat{l}_\beta = X \{Y(t) - \mu(t, X' \beta)\}' \Sigma^{-1} \mu_u(t, X' \beta), \\
\hat{l}_\alpha_k = X \rho_k (X' \alpha_k) \rho_k (X' \alpha_k) \phi_k (t)' \times \\
\left[-\Sigma^{-1} + \Sigma^{-1} \{Y(t) - \mu(t, X' \beta)\} \{Y(t) - \mu(t, X' \beta)\}' \Sigma^{-1} \right] \phi_k (t), \\
\hat{l}_{\sigma^2} = tr \left[-\frac{1}{2} \Sigma^{-1} + \frac{1}{2} \Sigma^{-1} \{Y(t) - \mu(t, X' \beta)\} \{Y(t) - \mu(t, X' \beta)\}' \Sigma^{-1} \right], \\
\hat{l}_\mu [h_1] = \{Y(t) - \mu(t, X' \beta)\}' \Sigma^{-1} h_1, \\
\hat{l}_\phi_k [h_{2,k}] = \rho_k (X' \alpha_k) \phi_k (t)' \left[-\Sigma^{-1} + \Sigma^{-1} \{Y(t) - \mu(t, X' \beta)\} \{Y(t) - \mu(t, X' \beta)\}' \Sigma^{-1} \right] h_{2,k}, \\
\hat{l}_\rho_k [h_{3,k}] = \phi_k (t)' \left[-\Sigma^{-1} + \Sigma^{-1} \{Y(t) - \mu(t, X' \beta)\} \{Y(t) - \mu(t, X' \beta)\}' \Sigma^{-1} \right] \phi_k (t) h_{3,k}, \\
\]

for \( k = 1, \ldots, K_n. \)

Define \( \Pi_n^\delta = A^\delta \times \Theta_n^\delta \times \Theta_{1n}^\delta \times \Theta_{2n}^\delta, \) where

\[ A^\delta = \{(\beta', \alpha', \sigma^2) : \|\beta - \beta_0\| < \delta, \|\alpha - \alpha_0\| < \delta, \|\sigma^2 - \sigma_0^2\| < \delta, (\beta', \alpha', \sigma^2) \in \mathcal{A}\}, \]

\[ \Theta_n^\delta = \{\mu(t, u) : \|\mu(t, u) - \mu_0(t, u)\| < \delta, \mu \in \Theta\}, \]

\[ \Theta_{1n}^\delta = \left\{\phi(t) : \|\phi(t) - \phi_0(t)\| < \delta, \phi(t) \in \prod_{k=1}^{K_n} \Theta_{1k} \right\}, \]

\[ \Theta_{2n}^\delta = \left\{\rho(u) : \|\rho(u) - \rho_0(u)\| < \delta, \rho(u) \in \prod_{k=1}^{K_n} \Theta_{2k} \right\}. \]

Let \( \|v\| \) denote the \( \ell_2 \) norm for a vector \( v \) and \( \|f\| = (\int_0^T f^2(t) dt)^{1/2} \) for any function \( f(\cdot) \) with a domain \([0, T]\); \( a \preceq b \) means \( c_1 \leq a/b \leq c_2, \) where \( c_2 > c_1 > 0 \) are constants and \( a \ll b \) means \( a/b \to 0. \)

**S3.2 Proofs of The Main Results**

**Lemma 1:** For \( \mu_0 \in \mathcal{H}_{r,2}, \phi_{k0}, \rho_{k0} \in \mathcal{H}_{r,1}, 1 \leq k \leq K_n, \) there exists smoothing spline \( \mu_n, \phi_{nk}, \rho_{nk} \) such that \( \|\mu_n - \mu_0\|_\infty = O(m_n^{-r}), \) \( \|\phi_{nk} - \phi_{k0}\|_\infty = O(m_n^{-r}), \) \( \|\rho_{nk} - \rho_{k0}\|_\infty = O(m_n^{-r}). \) Moreover, we have \( \|\pi_n - \pi_0\|_\infty = O(m_n^{-r}), \) where \( \pi_n = (\beta, \alpha', \sigma^2, \mu_n, \phi_n', \rho_n') \in \Pi_n. \)

**Lemma 2:** Let \( N(\varepsilon, \mathcal{F}, d) \) denote the covering number with respect to a semi-metric \( d \) of function class \( \mathcal{F} \). Under Conditions (C1)-(C3), the covering number of the class \( \mathcal{L}_n(\delta) = \{l(\pi) : \pi \in \Pi_n^\delta\} \) satisfies

\[
N(\varepsilon, \mathcal{L}_n(\delta), \| \cdot \|) \leq (\delta/\varepsilon)^{(Kn_m^2 + m^2_n)}.
\]

**Proof:** The proof is similar to that in Ma et al. (2015), and is omitted.

**Lemma 3:** Under (C1)-(C4), we have for any \( \delta \leq 1 \),

\[
\sup_{\pi \in \Pi_n^\delta} |\mathbb{P}_n l(\pi) - \mathbb{P} l(\pi)| \to 0
\]

almost surely.

**Proof:** Since \( \pi \in \Pi_n^\delta \), then \( |l(\pi)| \) is bounded. Without loss of generality, we assume \( \sup_{\pi \in \Pi_n^\delta} |l(\pi)| \leq 1 \). It then follows that \( \mathbb{P} l^2(\pi) \leq \mathbb{P} \sup_{\pi \in \Pi_n^\delta} |l(\pi)|^2 \leq 1 \). Let \( \max\{(v + \tau)/2, v\} < \phi < 1/2, \alpha_n = n^{-1/2+\phi} \log(n)^{1/2} \), and \( \varepsilon_n = \varepsilon \alpha_n \) for fixed \( \varepsilon > 0 \). Then for any \( l(\pi) \in \mathcal{L}_n(\delta) \) and sufficiently large \( n \), we have

\[
\text{Var}\{\mathbb{P}_n l(\pi)/(4\varepsilon_n)\} \leq \frac{\mathbb{P} l^2(\pi)}{16\varepsilon^2 n\alpha_n^2} \leq \frac{1}{16\varepsilon^2 \log n} \leq \frac{1}{2}.
\] (1)

By inequality (31) and lemma 33 in Pollard (1984) and Lemma 2, it yields

\[
P(\sup_{\pi \in \Pi_n^\delta} |\mathbb{P}_n l(\pi) - \mathbb{P} l(\pi)| > 8\varepsilon_n)
\leq 8N(\varepsilon, \mathcal{L}_n(\delta), \| \cdot \|) \exp(-\frac{n\varepsilon_n^2}{128}P(\sup_{\pi \in \Pi_n^\delta} |n^{-1} \sum_{i=1}^{n} l^2(\pi_n)| \leq 64) + P(\sup_{\pi \in \Pi_n^\delta} |n^{-1} \sum_{i=1}^{n} l^2(\pi_n)| > 64)
\leq \varepsilon_n^-(Kn_m^2 + m^2_n) \exp(-\frac{n\varepsilon_n^2\alpha_n^2}{128})
\leq \exp\{(Kn_m^2 + m^2_n) \log(\frac{1}{\varepsilon n^{-1/2+\phi} \log(n)^{1/2}}) - \frac{1}{128}n\varepsilon_n^2 n^{-1+2\phi} \log n\}
\leq \exp\left[(Kn_m^2 + m^2_n) \left\{ \left(\frac{1}{2} - \phi\right) \log n - \frac{1}{2} \log \log n + \log(1/\varepsilon) \right\} - \frac{1}{128}n\varepsilon_n^2 n^{-1+2\phi} \log(n)\right]
\leq \exp(-c^* n^{2\phi} \log n),
\] (2)
where \( c^* \) is a constant. Hence,

\[
\sum_{n=1}^{\infty} P(\sup_{\pi \in \Pi_n^*} |P_n l(\pi) - P l(\pi)| > 8 \varepsilon_n) < \infty. \tag{3}
\]

By the Borel-Cantelli lemma, we have

\[
P\left( \bigcap_{k=1}^{\infty} \bigcup_{n=k}^{\infty} \{ \sup_{\pi \in \Pi_n^*} |P_n l(\pi) - P l(\pi)| > 8 \varepsilon_n \} \right) = 0,
\]

meaning that the probability that events \( \{ \sup_{\pi \in \Pi_n^*} |P_n l(\pi) - P l(\pi)| > 8 \varepsilon_n \} \) will occur for infinite many times is 0. Since \( \varepsilon_n \to 0 \), this completes the proof.

S3.2.1 Proof of Theorem 3.1. Define \( \mathcal{N}_\epsilon = \{ \pi : \epsilon_0 > \|\pi - \pi_0\|, \pi \in \Pi_n^* \} \) for some \( \epsilon_0 \leq 1 \) and any \( 0 < \epsilon < \epsilon_0 \). Then we have

\[
\sup_{\mathcal{N}_\epsilon} P l(\pi) = \sup_{\mathcal{N}_\epsilon} \{ P l(\pi) - P_n l(\pi) + P_n l(\pi) \} \geq - \sup_{\mathcal{N}_\epsilon} |P_n l(\pi) - P l(\pi)| + \sup_{\mathcal{N}_\epsilon} P_n l(\pi) = - H_1 + \sup_{\mathcal{N}_\epsilon} P_n l(\pi), \tag{4}
\]

where \( H_1 = \sup_{\mathcal{N}_\epsilon} |P_n l(\pi) - P l(\pi)| \). For \( \hat{\pi}_n^* \in \mathcal{N}_\epsilon \), we have

\[
\sup_{\mathcal{N}_\epsilon} P_n l(\pi) = P_n l(\hat{\pi}_n^*) \geq P_n l(\pi_0) = - H_2 + P l(\pi_0), \tag{5}
\]

where \( H_2 = P l(\pi_0) - P_n l(\pi_0) \). Thus, (4) and (5) give

\[
P l(\pi_0) - \sup_{\mathcal{N}_\epsilon} P l(\pi) \leq H_1 + H_2. \tag{6}
\]

By Jensen’s inequality,

\[
P l(\pi) - P l(\pi_0) \leq \log \mathbb{P} \left\{ \frac{f(\pi)}{f(\pi_0)} \right\} = \log \int \frac{f(\pi)}{f(\pi_0)} f(\pi_0) dx = 0,
\]

where the equality holds if and only if \( \pi = \pi_0 \). Let \( \delta_\epsilon = P l(\pi_0) - \sup_{\mathcal{N}_\epsilon} P l(\pi) > 0 \). Since \( \{ \hat{\pi}_n^* \in \mathcal{N}_\epsilon \} \subseteq \{ H_1 + H_2 \geq \delta_\epsilon \} \), it follows that \( H_1 = o(1) \), \( H_2 = o(1) \) almost surely, by Lemma \ref{lemma} and the strong Law of Large Numbers. Therefore, \( \|\hat{\pi}_n^* - \pi_0\|_2 = o(1) \) almost surely.

We next conclude the convergence rate by verifying the conditions of Theorem 3.2.5 of
van der Varrt and Wellner (1996). To that end, we define a function class

\[ \mathcal{L}_\epsilon = \{ l(\pi) - l(\pi_0), \| \pi - \pi_0 \| \leq \epsilon, \pi \in \Pi'_n \}. \]

It can be seen that \( \log N[\| \epsilon, \mathcal{L}_\epsilon, \| \cdot \| ] \leq (K_n m_n + m_n^2) \log(\frac{r}{\epsilon}) \). Then the bracketing integral

\[ J[\| \epsilon, \mathcal{L}_\epsilon, \| \cdot \| ] = \int_0^\epsilon \sqrt{1 + \log N[\| \epsilon, \mathcal{L}_\epsilon, \| \cdot \| ]} d\epsilon \leq \sqrt{K_n m_n + m_n^2} \epsilon. \]

By Lemma 3.4.2 of van der Varrt and Wellner (1996), we have

\[ E \left( \sup_{\mathcal{L}_\epsilon} \sqrt{n} |\mathbb{P}_n - \mathbb{P}| (l(\pi) - l(\pi_0)) \right) \leq J[\| \epsilon, \mathcal{L}_\epsilon, \| \cdot \| ] \left( 1 + \frac{J[\| \epsilon, \mathcal{L}_\epsilon, \| \cdot \| ] M_0}{\epsilon^2 \sqrt{n}} \right) \]

\[ \leq O(\sqrt{K_n m_n + m_n^2} \epsilon + \frac{K_n m_n + m_n^2}{\sqrt{n}}). \quad (7) \]

This shows that the function \( \phi_n(\epsilon) \) in Theorem 3.2.5 of van der Varrt and Wellner (1996) is given by \( \phi_n(\epsilon) = \sqrt{K_n m_n + m_n^2} \epsilon + \frac{K_n m_n + m_n^2}{\sqrt{n}} \). Obviously, \( \phi_n(\epsilon)/\epsilon \) is decreasing in \( \epsilon \) and 

\[ r_n^2 \phi_n(\frac{1}{r_n}) = r_n \sqrt{K_n m_n + m_n^2} + \frac{r_n^2(K_n m_n + m_n^2)}{\sqrt{n}} \leq \sqrt{n} \]

for every \( n \), which implies \( r_n \leq \sqrt{n}/\sqrt{K_n m_n + m_n^2} \).

Besides, we need to show that \( \tilde{\pi}'_n \) satisfies \( \mathbb{P}_n l(\tilde{\pi}'_n) \geq \mathbb{P}_n l(\pi_0) - O_p(r_n^{-2}) \). Note that

\[ \mathbb{P}_n l(\tilde{\pi}'_n) - \mathbb{P}_n l(\pi_0) = \mathbb{P}_n (l(\tilde{\pi}'_n) - l(\pi_0)) + (\mathbb{P}_n - \mathbb{P}) (l(\pi_0) - l(\pi_0)) + \mathbb{P} (l(\pi_n) - l(\pi_0)) \]

\[ = I_1 + I_2 + I_3, \]

where \( I_1 > 0 \). Define \( \tilde{L}(\pi) = \{ \frac{l(\pi) - l(\pi_0)}{n^{-1/2}} \pi, \pi \in \Pi'_n \} \), which is a P-Donsker class by Lemma 1.

Therefore, \( I_2 = O_p(n^{-rv+\tau/2} n^{-1/2}) \) and \( I_3 \geq -O_p(n^{-2rv+\tau}) \). Since \( \epsilon < 1/2 - vr + \tau/2 \), it follows \( \mathbb{P}_n l(\tilde{\pi}'_n) - \mathbb{P}_n (\pi_0) \geq -O_p(n^{-2rv+\tau}) \) for \( r_n \leq n^{1/r-\tau/2} \).

Finally, we obtain that

\[ \| \tilde{\pi}'_n - \pi_0 \| = O_p(r_n^{-1}) = O_p(\delta_n) \]

with \( \delta_n = n^{-(1-2v)/2} + n^{-(1-v-\tau)/2} + n^{-(v-\tau)/2} \) by noting \( K_n = n^\tau \). This completes the proof.
S3.2.2 Proof of Theorem 3.2. Denote

\[ S_{1n}(\pi) = \mathbb{P}_n l_1(\pi), S_{2n}(\pi)[h] = \mathbb{P}_n l_2(\pi)[h], \]
\[ S_1(\pi) = \mathbb{P} l_1(\pi), S_2(\pi)[h] = \mathbb{P} l_2(\pi)[h]. \]

From the definitions of \( l_1(\pi) \) and \( l_2(\pi) \), it follows
\[ S_1(\pi_0) = 0 \quad \text{and} \quad S_2(\pi_0)[h] = 0. \]

Define
\[ \dot{S}_{11}(\pi) = -\mathbb{P} l_1(\pi) l_1(\pi)', \]
\[ \dot{S}_{12}(\pi)[h] = \dot{S}_{21}(\pi)[h] - \mathbb{P} l_1(\pi) l_2(\pi)[h], \]
\[ \dot{S}_{22}(\pi)[h^*, h] = -\mathbb{P} l_2(\pi)[h^*] l_2(\pi)[h] \]
for \( h^*, h \in R \times \mathcal{H}_{r,2} \times \prod_{j=1}^{K_n} \mathcal{H}_{r,1} \times \prod_{j=1}^{K_n} \mathcal{H}_{r,1}. \) To prove the theorem, we need to show

(a) There is an \( h^* \in R \times \mathcal{H}_{r,2} \times \prod_{j=1}^{K_n} \mathcal{H}_{r,1} \times \mathcal{H}_{r,1} \) such that
\[ \dot{S}_{12}(\pi_0)[h] - \dot{S}_{22}(\pi_0)[h^*, h] = 0, \] (8)

and
\[ I(\vartheta) = -\dot{S}_{11}(\pi) + \dot{S}_{21}(\pi)[h^*] \] (9)

is the information for estimation of \( \vartheta \) with \( I^{-1}(\vartheta) \) being the information bound for \( h \in R \times \mathcal{H}_{r,2} \times \prod_{j=1}^{K_n} \mathcal{H}_{r,1} \times \prod_{j=1}^{K_n} \mathcal{H}_{r,1}. \)

(b) Stochastic equicontinuity, i.e.,
\[ \sup_{\|\pi - \pi_0\| \leq \delta_n} |\sqrt{n}(S_{1n} - S_1(\pi)) - \sqrt{n}(S_{1n} - S_1(\pi_0))| = o_p(1), \] (10)
and

$$\sup_{\|\pi - \pi_0\| \leq \delta_n} |\sqrt{n}(S_{2n} - S_2)(\pi)[h^*] - \sqrt{n}(S_{2n} - S_2)(\pi_0)[h^*]| = o_p(1),$$

(11)

when $0 < v < 1/4, \tau < \min\{1/2 - v, 2v(r - 1), v(2r - 1)/2\}$.

(c) In a neighborhood $\{\pi : \|\pi - \pi_0\| \leq \delta_n\}$ and for $r > 1$,

$$S_1(\pi) - S_1(\pi_0) - \dot{S}_{11}(\pi_0)[\vartheta - \vartheta_0] - \dot{S}_{12}(\pi_0)[\psi - \psi_0]$$

$$= o(\|\vartheta - \vartheta_0\|) + O(\|\psi - \psi_0\|^2),$$

(12)

and

$$S_2(\pi)[h^*] - S_2(\pi_0)[h^*] - \dot{S}_{21}(\pi_0)[\vartheta - \vartheta_0] - \dot{S}_{22}(\pi_0)[h^*, \psi - \psi_0]$$

$$= o(\|\vartheta - \vartheta_0\|) + O(\|\psi - \psi_0\|^2).$$

(13)

We first verify (a). In fact,

$$\dot{S}_{12}(\pi_0)[h] - \dot{S}_{22}(\pi_0)[h^*, h] = -P{l_1}(\pi_0)l_2(\pi_0)[h] + P{l_2}(\pi_0)[h^*]l_2(\pi_0)[h]$$

$$= -P\{l_1(\pi_0) - l_2(\pi_0)[h^*]\}l_2(\pi_0)[h],$$

where $h^* = E(l_1(\pi_0)[X, Y])/E(l_2(\pi_0)[X, Y])$ satisfies $\dot{S}_{12}(\pi_0)[h] - \dot{S}_{22}(\pi_0)[h^*, h] = 0$.

Denote $l^*(\pi) = l_1(\pi) - l_2(\pi)[h^*]$ to be the efficient score for $\vartheta$. Then

$$I(\vartheta) = -\dot{S}_{11}(\pi) + \dot{S}_{21}(\pi)[h^*]$$

$$= P{l_1}(\pi)[l_1(\pi)] - P{l_2}(\pi)[h^*]l_1(\pi)$$

$$= P\{l_1(\pi) - l_2(\pi)[h^*]\}l_1(\pi)$$

$$= P\{l^*(\pi)\} \otimes 2.$$
Then for (b), by the definitions of $S_{1n}, S_1, S_{2n},$ and $S_2$, we have
\[
\sqrt{n}(S_{1n} - S_1)(\pi) - \sqrt{n}(S_{1n} - S_1)(\pi_0) = \sqrt{n}(\mathbb{P}_n - \mathbb{P})(l_1(\pi) - l_1(\pi_0)),
\]
and
\[
\sqrt{n}(S_{2n} - S_2)(\pi)[h^*] - \sqrt{n}(S_{2n} - S_2)(\pi_0)[h^*] = \sqrt{n}(\mathbb{P}_n - \mathbb{P})(l_2(\pi)[h^*] - l_2(\pi_0)[h^*]).
\]
Considering the classes of functions \(\{l_1(\pi) : \|\pi - \pi_0\| \leq \delta_n\}\) and \(\{l_2(\pi)[h^*] : \|\pi - \pi_0\| \leq \delta_n\}\), it yields
\[
E\left( \sup_{\|\pi - \pi_0\| \leq \delta_n} |\sqrt{n}(\mathbb{P}_n - \mathbb{P})(l_1(\pi) - l_1(\pi_0))| \right) \leq O\left(\sqrt{K_n m_n + m_n^2 \delta_n} + \frac{K_n m_n + m_n^2}{\sqrt{n}}\right) = o(1),
\]
when when \(0 < v < 1/4, \tau < \min\{1/2 - v, 2v(r - 1), v(2r - 1)/2\}\) for \(r > 1\). Thus, we have
\[
\sup_{\|\pi - \pi_0\| \leq \delta_n} |\sqrt{n}(\mathbb{P}_n - \mathbb{P})(l_1(\pi) - l_1(\pi_0))| \to 0.
\]
Similarly,
\[
\sup_{\|\pi - \pi_0\| \leq \delta_n} |\sqrt{n}(\mathbb{P}_n - \mathbb{P})(l_2(\pi)[h^*] - l_2(\pi_0)[h^*])| \to 0.
\]
Finally, for (c),
\[
S_1(\pi) - S_1(\pi_0) = \hat{S}_{11}(\pi_0)[\theta - \theta_0] + \hat{S}_{12}(\pi_0)[\psi - \psi_0] + \hat{S}_{11}(\pi)[\theta - \theta_0] + \hat{S}_{12}(\pi)[\psi - \psi_0] - (\hat{S}_{11}(\pi_0)[\theta - \theta_0] + \hat{S}_{12}(\pi_0)[\psi - \psi_0])
\]
\[
= \hat{S}_{11}(\pi_0)[\theta - \theta_0] + \hat{S}_{12}(\pi_0)[\psi - \psi_0] + O(\|\theta - \theta_0\|^2) + O(\|\psi - \psi_0\|^2).
\]
Similarly,
\[
S_2(\pi)[h^*] - S_2(\pi_0)[h^*] = \hat{S}_{21}(\pi_0)[\theta - \theta_0] + \hat{S}_{22}(\pi_0)[\psi - \psi_0]
\]
\[
= O(\|\theta - \theta_0\|^2) + O(\|\psi - \psi_0\|^2).
\]
Now we are positioned to conclude the normality of $\hat{\theta}_n^{or}$. First, note that
\[
S_{1n}(\hat{\pi}_n^{or}) = 0, S_{2n}(\hat{\pi}_n^{or})[h^*] = 0 \quad \text{and} \quad S_1(\pi_0) = 0, S_2(\pi_0)[h^*] = 0.
\] (14)
For $\mathbf{h}_n^* \in R \times \Theta \times \prod_{k=1}^{K_n} \Theta_{1k} \times \Theta_{2n}^*$ and $\|\mathbf{h}^* - \mathbf{h}_n^*\| = O(n^{-\alpha+\alpha/2})$, under the condition in (b) and by some entropy calculation, we have $S_{2n}(\hat{\mathbf{h}}_n^*) = o_p(n^{-1/2})$.

Then we see that

$$\hat{S}_{11}(\hat{\mathbf{v}}_n^* - \mathbf{v}_0) + \hat{S}_{12}(\hat{\mathbf{u}}_n^* - \mathbf{u}_0) + o(||\hat{\mathbf{v}}_n^* - \mathbf{v}_0||) + O(||\hat{\mathbf{u}}_n^* - \mathbf{u}_0||^2) - S_{1n}(\mathbf{v}_0) = o_p(n^{-1/2}),$$

$$\hat{S}_{21}[\mathbf{h}^*](\hat{\mathbf{v}}_n^* - \mathbf{v}_0) + \hat{S}_{12}[\mathbf{h}, \hat{\mathbf{u}}_n^* - \mathbf{u}_0] + o(||\hat{\mathbf{u}}_n^* - \mathbf{u}_0||) + O(||\hat{\mathbf{u}}_n^* - \mathbf{u}_0||^2) - S_{2n}(\mathbf{v}_0)[\mathbf{h}^*] = o_p(n^{-1/2}),$$

by (14), (b) and (c).

We then have

$$(\hat{S}_{11} - \hat{S}_{21}[\mathbf{h}^*])(\hat{\mathbf{v}}_n^* - \mathbf{v}_0) + o(||\hat{\mathbf{v}}_n^* - \mathbf{v}_0||) = S_{1n}(\mathbf{v}_0) - S_{2n}(\mathbf{v}_0)[\mathbf{h}^*] + o_p(n^{-1/2}),$$

by (a) and (15). This yields that

$$\sqrt{n}(\hat{S}_{11} - \hat{S}_{21}[\mathbf{h}^*])(\hat{\mathbf{v}}_n^* - \mathbf{v}_0) = \sqrt{n}\{S_{1n}(\mathbf{v}_0) - S_{2n}(\mathbf{v}_0)[\mathbf{h}^*]\} + o_p(1)$$

$$= \sqrt{n} \mathbb{P}_n l^*(\mathbf{v}_0) + o_p(1).$$

Besides, note that when $n^{\gamma-1/2}/\Lambda = o_p(1)$, where $\Lambda = \lambda_{\min}(I(\mathbf{v}_0))$,

$$\mathbf{u}'I(\mathbf{v}_0)^{1/2} \mathbb{P}_n l^*(\mathbf{v}_0)\otimes 2 - I(\mathbf{v}_0) = 1 + \mathbf{u}'I(\mathbf{v}_0)^{1/2}(\mathbb{P}_n l^*(\mathbf{v}_0)\otimes 2 - I(\mathbf{v}_0))I(\mathbf{v}_0)^{1/2}\mathbf{u},$$

where the second term is bounded by

$$\|I(\mathbf{v}_0)^{1/2}\|\|\mathbb{P}_n l^*(\mathbf{v}_0)\otimes 2 - I(\mathbf{v}_0)\|\|I(\mathbf{v}_0)^{1/2}\| = \Lambda^{-1/2}O_p(n^{\gamma}n^{-1/2})\Lambda^{-1/2} = o_p(1).$$

Therefore, it follows for any vector $\mathbf{u}$ with $\|\mathbf{u}\| = 1$,

$$\sqrt{n}\mathbf{u}'I(\mathbf{v}_0)^{1/2}(\hat{\mathbf{v}}_n^* - \mathbf{v}_0) \to N(0, 1).$$

This completes the proof of Theorem 3.2.

**S3.2.3 Proof of Theorem 3.3.** We show that $\hat{\mathbf{h}}_n^*$ is a strict minimum of $Q_n(\mathbf{v})$ for $\mathbf{v} \in \Pi_n$ with probability approaching 1 through the following two steps.
(1) For any $\pi \in \Pi_n^\delta$, denote $\pi^* = (\beta', \alpha^*, \sigma^2, \mu, \rho^*, \phi)' \in \Pi_n^{or}$, where $\rho^* = T(\rho)$ and $\rho^*_{ik} = \rho_k(X_i' \alpha_k^*)$,

$$Q_n(\pi^*) \leq Q_n(\hat{\pi}_{n}^{or}),$$

with the equality only when $\pi^* = \hat{\pi}_{n}^{or}$.

(2) Define $\tilde{\Pi}_n = \{\pi : \|\pi - \hat{\pi}_{n}^{or}\| \leq t_n, \pi \in \Pi_n^\delta\}$, where $t_n$ is a positive sequence. For any $\pi \in \Pi_n^\delta \cup \tilde{\Pi}_n$,

$$Q_n(\pi) \leq Q_n(\pi^*),$$

with the equality only when $\pi = \pi^*$.

We first show (1). Under condition (C4) and $\sup_{(i,k) \in O} |\rho_{ik0}| > a\lambda$,

$$|\rho_{ik}| \geq |\rho_{ik} - \rho_{ik0}| \geq |\rho_{ik0}| - \delta_n > a\lambda,$$

when $\lambda \gg \delta_n$. Thus,

$$\sum_{i,k} p_\lambda(|\rho_{ik}^*|) = \sum_{(i,k) \in O} p_\lambda(|\rho_{ik}|) = c_1,$$

(16)

where $c_1$ is a constant not depend on $\pi$. In addition, for any $\pi \in \Pi_n^\delta$, by the definition of $\hat{\pi}_{n}^{or}$, we have $L_n(\hat{\pi}_{n}^{or}) \geq L_n(\pi^*)$. Therefore, it follows $Q_n(\pi^*) = L_n(\pi^*) + c_1$ and $Q_n(\hat{\pi}_{n}^{or}) = L_n(\hat{\pi}_{n}^{or}) + c_1$. Hence we get

$$Q_n(\pi^*) \leq Q_n(\hat{\pi}_{n}^{or}).$$

Next we show (2). For any $\pi \in \Pi_n^\delta \cup \tilde{\Pi}_n$, by Taylor’s expansion, we have

$$Q_n(\pi^*) - Q_n(\pi) = L_n(\pi^*) - L_n(\pi) - \left\{ \sum_{i,k} p_\lambda(|\rho_{ik}^*|) - \sum_{i,k} p_\lambda(|\rho_{ik}|) \right\}$$

$$= \left\{ \frac{\partial L_n(\pi)}{\partial \rho} \right\}'(\rho^* - \rho) - \sum_{i,k} p_\lambda(|\rho_{ik}^*|)(|\rho_{ik}^* - \rho_{ik}|)$$

$$= H_1 + H_2,$$
where \( \tilde{\rho}_{ik} \) lies between \( \rho_{ik}^* \) and \( \rho_{ik} \). For \( H_2 \), it can be seen that

\[
H_2 = - \sum_{i,k} \dot{p}_\lambda(|\tilde{\rho}_{ik}|)(|\rho_{ik}^* - \rho_{ik}|) \\
= - \sum_{(i,k) \in O} \dot{p}_\lambda(|\tilde{\rho}_{ik}|)(|\rho_{ik}^* - \rho_{ik}|) - \sum_{(i,k) \notin O} \dot{p}_\lambda(|\tilde{\rho}_{ik}|)(|\rho_{ik}^* - \rho_{ik}|) \\
= - \sum_{(i,k) \in O} \dot{p}_\lambda(|\tilde{\rho}_{ik}|)(|\rho_{ik}^* - \rho_{ik}|) + \sum_{(i,k) \notin O} \dot{p}_\lambda(|\tilde{\rho}_{ik}|)|\rho_{ik}|.
\]

Similar to (16), \( \dot{p}_\lambda(|\tilde{\rho}_{ik}|) \) in the first term is equal to 0. Thus, the first term in \( H_2 \) disappears. For the second term in \( H_2 \), noting \( |\tilde{\rho}_{ik}| \leq |\rho_{ik}| \leq |\rho_{ik} - \tilde{\rho}_{ik}^\ast| + |\tilde{\rho}_{ik}^\ast| \leq t_n \) for \((i,k) \notin O\), we get

\[
H_2 \geq \sum_{(i,k) \notin O} \dot{p}_\lambda(t_n)|\rho_{ik}|,
\]

by the concavity of \( p_\lambda(t) \).

For \( H_1 \), by Taylor’s expansion, we have

\[
H_1 = \sum_{i,k} \left\{ \frac{\partial L_n(\tilde{\pi})}{\partial \rho_{ik}} \right\}' (\rho_{ik}^* - \rho_{ik}) \\
\leq \sum_{i,k} \left\{ c_3P \frac{\partial L_n(\tilde{\pi})}{\partial \rho_{ik}} \right\}' (\rho_{ik}^* - \rho_{ik}) \\
= \sum_{(i,k) \notin O} \left[ c \left\{ \frac{\partial L_n(\pi_0)}{\partial \rho_{ik}} + \frac{\partial^2 L_n(\pi_0)}{\partial \rho_{ik}^2} (\tilde{\rho}_{ik} - \rho_{ik0})(1 + o_p(1)) \right\} \right] (-\rho_{ik}) \\
\leq \sum_{(i,k) \notin O} O_p(t_n + \delta_n)(-\rho_{ik}).
\]

The last inequality is because \( |\tilde{\rho}_{ik} - \rho_{ik0}| \leq |\tilde{\rho}_{ik} - \rho_{ik}| + |\rho_{ik} - \rho_{ik0}| \leq t_n + \delta_n \) and \( \lambda_{\text{max}} \{ \mathbb{E} \frac{\partial^2 L_n(\pi_0)}{\partial \rho \partial \rho'} \} < \infty \). Thus, \( H_1 \geq - \sum_{(i,k) \notin O} O_p(t_n + \delta_n)|\rho_{ik}| \). Combining with (17), we have

\[
Q_n(\pi^\ast) - Q_n(\pi) \geq \sum_{(i,k) \notin O} \{ \dot{p}_\lambda(t_n) - O_p(t_n + \delta_n) \} |\rho_{ik}|.
\]

Taking \( t_n = o(\lambda) \), we get \( \dot{p}_\lambda(t_n) \to \lambda \). Since \( \lambda \gg \delta_n \), for sufficiently large \( n \), we have \( Q_n(\pi^\ast) \geq Q_n(\pi) \). This completes the proof of Theorem 3.3.

**S3.2.4 Proof of Theorem 3.4.** Theorem 3.4 is a standard result of semiparametric M-estimation, which can be referred to Theorem 1 in Cheng and Huang (2010). The proofs of
**Supporting Information for 'Functional data analysis with covariate-dependent mean and covariance structures' by**

$\beta$ and $\alpha$ are similar. So we only consider the proof of $\beta$ in the following by verifying the conditions of Theorem 1 in [Cheng and Huang (2010)](https://doi.org/10.1214/10-AOS867).

We define $\Psi = (\alpha', \sigma^2, \mu, \phi', \rho')'$ is the other parametric which is infinite. Rewrite $\pi = (\beta', \Psi')'$. First, Condition I in [Cheng and Huang (2010)](https://doi.org/10.1214/10-AOS867) is satisfied, which means that the expectation of the derivative of score function and the variance of score function are both nonsingular. In addition, Conditions (W1)-(W5) in [Cheng and Huang (2010)](https://doi.org/10.1214/10-AOS867) are satisfied because it’s an exchangeable bootstrap and $c = 1$ under the notation in [Cheng and Huang (2010)](https://doi.org/10.1214/10-AOS867). Therefore, it suffices to verify Conditions (S1)-(S3) and (SB1)-(SB3).

Conditions (S1), (S2), (SB1) and (SB2) follow by Conditions (C1) ad (C2). For Condition (S3), recall that $\|\hat{\Psi}_n - \Psi_0\| = O_p(\delta_n)$ and $\|\hat{\beta}_n - \beta_0\| = n^{-1/2}$. If $\tau + v < 1/2$, there exists $\gamma \in (1/4, 1/2]$ satisfying Condition (S3). For Condition (SB3), we note $E(l(\beta, \Psi) - l(\beta_0, \Psi_0)) \leq -d^2(\Psi, \Psi_0) - \|\beta - \beta_0\|^2$ and $E(l(\beta, \Psi_0) - l(\beta_0, \Psi_0)) \geq -\|\beta - \beta_0\|^2$. Thus, we have

$$E(l(\beta, \Psi) - l(\beta, \Psi_0)) \leq E(l(\beta, \Psi) - l(\beta_0, \Psi_0)) - E(l(\beta, \Psi_0) - l(\beta_0, \Psi_0)) \leq -d^2(\Psi, \Psi_0) + \|\beta - \beta_0\|^2. \quad (19)$$

Denote $V_\delta = \{l(\beta, \Psi) - l(\beta_0, \Psi_0) : \pi = (\beta', \Psi')' \in \Pi_n^\delta\}$ and its bracketing entropy integral is $J_{\|, \delta, V_\delta, \| \cdot \|} \leq \sqrt{K_n m_n + m_n^2 \delta}$. Then, similar as [7], we have

$$E\left(\sup_{V_\delta} \sqrt{n}(\mathbb{P}_n - \mathbb{P})(l(\beta, \Psi) - l(\beta, \Psi_0))\right) \leq O\left(\sqrt{K_n m_n + m_n^2 \delta + \frac{K_n m_n + m_n^2}{\sqrt{n}}}\right), \quad (20)$$

and

$$E\left(\sup_{V_\delta} \sqrt{n}(\mathbb{P}_n^* - \mathbb{P})(l(\beta, \Psi) - l(\beta, \Psi_0))\right) \leq O\left(\sqrt{K_n m_n + m_n^2 \delta + \frac{K_n m_n + m_n^2}{\sqrt{n}}}\right), \quad (21)$$

where $\mathbb{P}_n^*$ is empirical measure under bootstrap samples satisfying Theorem 3 of [Cheng and Huang (2010)](https://doi.org/10.1214/10-AOS867). So Condition (SB3) follows by [19]-[21]. This completes of the proof.
