SUMMARY: We present the technical proofs of Theorem 1 in the main text and the lemmas used for the theorem in Web Appendix A. Additional simulation results and descriptive statistics for the Boston Lung Cancer Survivor Cohort are provided in Web Appendix B and Web Appendix C, respectively. Web Appendix D entails additional discussion on the difference between sparsity assumptions in our work and van de Geer et al. (2014).

This paper has been submitted for consideration for publication in Biometrics
Web Appendix A. Technical proofs

Web Appendix A.1 Lemmas

We list three lemmas that are used for proving Theorem 1. Without loss of generality, we denote the dimension of the parameter $\xi$ by $p$ instead of $(p + 1)$ to simplify the notation in the proofs. Consequently, the matrices such as $\Sigma_\xi$ and $\Theta_\xi$ are considered as $p \times p$ matrices. This simplification of notation does not affect the following derivations.

Lemma 1 bounds the estimation error and the prediction error of the lasso estimator under our assumptions.

**Lemma 1:** Under Assumptions 1–5, we have $\|\hat{\xi} - \xi^0\|_1 = O_P(s_0 \lambda)$ and $\|X(\hat{\xi} - \xi^0)\|_2^2/n = O_P(s_0 \lambda^2)$.

**Proof.** Because $\lambda_{\min}(\Sigma_{\xi^0}) > 0$ in Assumption 2, the compatibility condition holds for all index sets $S \subset \{1, \ldots, p\}$ by Lemma 6.23 (Bühlmann and van de Geer, 2011) and the fact that the adaptive restricted eigenvalue condition implies the compatibility condition. Exploiting Hoeffding’s concentration inequality, we have $\|\hat{\Sigma}_{\xi^0} - \Sigma_{\xi^0}\|_\infty = O_P[\{log(p)/n\}^{1/2}]$. Then by Lemma 6.17 of Bühlmann and van de Geer (2011), we have the $\hat{\Sigma}_{\xi^0}$-compatibility condition. Finally, the first part of Lemma 1 follows from Theorem 6.4 in Bühlmann and van de Geer (2011).

For the second claim, Ning and Liu (2017) showed that

$$(\hat{\xi} - \xi^0)^T \hat{\Sigma}_{\xi^0}(\hat{\xi} - \xi^0) = (\hat{\xi} - \xi^0)^T (X^T W_{\xi^0}^2 X/n)(\hat{\xi} - \xi^0) = O_P(s_0 \lambda^2),$$

then under Assumption 4, the variance terms in $W_{\xi^0}^2$ are bounded away from 0, and we obtain the desired result that $\|X(\hat{\xi} - \xi^0)\|_2^2/n = O_P(s_0 \lambda^2)$.

Lemma 2 depicts the convergence rate of the inverse Hessian matrix $\hat{\Theta}$ to the true inverse information matrix $\Theta_{\xi^0}$.

**Lemma 2:** Suppose the covariate vectors $x_i$, $i = 1, \ldots, n$, are independent and identically distributed sub-Gaussian random vectors. Under Assumptions 1–5, if we further assume that
\( s_0 \lambda \to 0 \) and \( p/n \to 0 \), then \( \hat{\Theta} \) converges to \( \Theta_{\xi^0} \) such that
\[
\| \hat{\Theta} - \Theta_{\xi^0} \| = \mathcal{O}_P\{(p/n)^{1/2} + s_0 \lambda \}.
\]

**Proof.** Since \( \hat{\Sigma}_{\xi}^{-1} - \Sigma_{\xi^0}^{-1} = \hat{\Sigma}_{\xi}^{-1} \left( \Sigma_{\xi^0} - \hat{\Sigma}_{\xi} \right) \Sigma_{\xi^0}^{-1} \), we have
\[
| \| \hat{\Sigma}_{\xi}^{-1} - \Sigma_{\xi^0}^{-1} \| | \leq | \| \hat{\Sigma}_{\xi}^{-1} \| | \cdot | \| \Sigma_{\xi^0} - \hat{\Sigma}_{\xi} \| | \cdot | \| \Sigma_{\xi^0}^{-1} \| |.
\]
By Assumption 2, \( | \| \Sigma_{\xi^0}^{-1} \| | \) is bounded. We obtain the convergence rate of \( | \| \hat{\Sigma}_{\xi}^{-1} - \Sigma_{\xi^0}^{-1} \| | \) by calculating the convergence rate of \( | \| \hat{\Sigma}_{\xi} - \Sigma_{\xi^0} \| | \) and showing that \( | \| \hat{\Sigma}_{\xi}^{-1} \| | \) is bounded with probability going to 1.

Note that \( | \| \hat{\Sigma}_{\xi} - \Sigma_{\xi^0} \| | \leq | \| \hat{\Sigma}_{\xi} - \Sigma_{\xi^0} \| | + | \| \Sigma_{\xi^0} - \hat{\Sigma}_{\xi} \| | \). When the rows of \( X \) are sub-Gaussian, so are the rows of \( X_{\xi^0} \) due to the boundedness of the weights \( w_i \) in Assumption 3. It can be shown that \( L = | \| \Sigma_{\xi^0}^{-1/2} x_1 \omega_1(\xi^0) \| \|_{\psi_2} = \mathcal{O}(1) \). First, for \( | \| \hat{\Sigma}_{\xi^0} - \Sigma_{\xi^0} \| | \), Vershynin (2012) shows that for every \( t > 0 \), it holds with probability at least \( 1 - 2 \exp(-c'_L t^2) \) that
\[
| \| \hat{\Sigma}_{\xi^0} - \Sigma_{\xi^0} \| | \leq | \| \Sigma_{\xi^0} \| | \max(\delta, \delta^2) \leq c_{\max} \max(\delta, \delta^2),
\]
where \( \delta = C_L(p/n)^{1/2} + t/n^{1/2} \). Here \( C_L, c'_L > 0 \) depend only on \( L = | \| \Sigma_{\xi^0}^{-1/2} x_1 \omega_1(\xi^0) \| \|_{\psi_2} \).

In fact \( c'_L = c_1/L^4 \) and \( C_L = L^2(\log 9/c_1)^{1/2} \), where \( c_1 \) is an absolute constant. For \( s > 0 \) and \( t = sC_L p^{1/2} \), the probability becomes \( 1 - 2 \exp(-c_2 s^2 p) \), \( c_2 > 0 \) being some absolute constant, and \( \delta = (s + 1)C_L(p/n)^{1/2} \). Thus \( | \| \hat{\Sigma}_{\xi^0} - \Sigma_{\xi^0} \| | = \mathcal{O}_P\{L^2(p/n)^{1/2}\} = \mathcal{O}_P\{(p/n)^{1/2}\} \).

Note that
\[
| \| \hat{\Sigma}_{\xi} - \Sigma_{\xi^0} \| | = | | X^T (W_{\xi}^2 - W_{\xi^0}^2) X / n | |
\leq | | X^T | | \cdot | | X / n \cdot | | W_{\xi}^2 - W_{\xi^0}^2 | |
= \lambda_{\max}(X^T X / n) \cdot | | W_{\xi}^2 - W_{\xi^0}^2 | |.
\]
By Assumptions 1 and 3,
\[
| | W_{\xi}^2 - W_{\xi^0}^2 | | = \max_i | \hat{\rho}(y_i, x_i^T \hat{\xi}) - \hat{\rho}(y_i, x_i^T \xi^0) | |
\leq c_{\text{Lip}} \cdot \max_i | x_i^T (\hat{\xi} - \xi^0) | 
\leq c_{\text{Lip}} K \cdot | | \hat{\xi} - \xi^0 | |.
\]
By Lemma 1, we have \( | | \hat{\xi} - \xi^0 | | = \mathcal{O}_P(s_0 \lambda) \). In this case, \( | | W_{\xi}^2 - W_{\xi^0}^2 | | = \mathcal{O}_P(s_0 \lambda) \). By Assumption
and Vershynin (2012), \(\lambda_{\max}(X^TX/n) = O_P(1)\). Thus \(\|\hat{\Sigma}_\xi - \hat{\Sigma}_{\xi^0}\| = O_P(s_0\lambda)\). Therefore, after combining the two parts, we have \(\|\hat{\Sigma}_\xi - \Sigma_{\xi^0}\| = O_P\{L^2(p/n)^{1/2} + s_0\lambda\}\). Under \(p/n = o(1)\) and \(s_0\lambda = o(1)\), we have \(\|\hat{\Sigma}_\xi - \Sigma_{\xi^0}\| = o_P(1)\).

Now for any vector \(x\) with \(\|x\|_2 = 1\), we have

\[
\inf_{\|y\|_2 = 1} \|\hat{\Sigma}_\xi y\|_2 \leq \|\hat{\Sigma}_\xi x\|_2 \leq \|\Sigma_{\xi^0}x\|_2 + \sup_{\|z\|_2 = 1} \|\hat{\Sigma}_\xi - \Sigma_{\xi^0}\|_2 \|z\|_2,
\]

which indicates that \(\lambda_{\min}(\hat{\Sigma}_\xi) \leq \lambda_{\min}(\Sigma_{\xi^0}) + \|\hat{\Sigma}_\xi - \Sigma_{\xi^0}\|\). Similarly, we have \(\lambda_{\min}(\Sigma_{\xi^0}) \leq \lambda_{\min}(\Sigma_{\xi^0}) + \|\hat{\Sigma}_\xi - \Sigma_{\xi^0}\|\). So \(\lambda_{\min}(\Sigma_{\xi^0}) - \lambda_{\min}(\hat{\Sigma}_\xi) \leq \|\hat{\Sigma}_\xi - \Sigma_{\xi^0}\|\). Thus, for any \(0 < \epsilon < \min\{\|\Sigma_{\xi^0}\|, \lambda_{\min}(\Sigma_{\xi^0})/2\}\), we have that

\[
pr\left(\|\hat{\Sigma}_\xi^{-1}\| \geq \frac{1}{\lambda_{\min}(\Sigma_{\xi^0}) - \epsilon}\right) = pr(\lambda_{\min}(\hat{\Sigma}_\xi) \leq \lambda_{\min}(\Sigma_{\xi^0}) - \epsilon)
\]

\[
\leq pr(|\lambda_{\min}(\hat{\Sigma}_\xi) - \lambda_{\min}(\Sigma_{\xi^0})| \geq \epsilon)
\]

\[
\leq pr(\|\hat{\Sigma}_\xi - \Sigma_{\xi^0}\| \geq \epsilon).
\]

Since \(\|\hat{\Sigma}_\xi - \Sigma_{\xi^0}\| = o_P(1)\), we have \(\|\hat{\Sigma}_\xi^{-1}\| = O_P(1)\). Finally, by (1), \(\|\hat{\Sigma}_\xi^{-1} - \Sigma_{\xi^0}^{-1}\| = O_P(\|\hat{\Sigma}_\xi - \Sigma_{\xi^0}\|) = O_P\{(p/n)^{1/2} + s_0\lambda\}\).

**Lemma 3:** Under Assumptions 1–3, when \(p/n \to 0\), it holds that for any vector \(\alpha_n \in \mathbb{R}^p\) with \(\|\alpha_n\|_2 = 1\),

\[
n^{-1/2}\alpha_n^T\Theta_{\xi^0}P_n\hat{\rho}_{\xi^0}^n(\alpha_n^T\Theta_{\xi^0}\alpha_n)^{1/2} \to N(0, 1)
\]

in distribution as \(n \to \infty\).

**Proof.** We invoke the Lindeberg-Feller Central Limit Theorem. For \(i = 1, \ldots, n\), let

\[
Z_{ni} = n^{-1/2}\alpha_n^T\Theta_{\xi^0}\hat{\rho}_{\xi^0}(y_i, x_i) = n^{-1/2}\alpha_n^T\Theta_{\xi^0}x_i\hat{\rho}(y_i, x_i^T\xi^0),
\]

and \(s_n^2 = \text{Var}\{\sum_{i=1}^n Z_{ni}\}\). Note that \(E\{\hat{\rho}(y_i, x_i^T\xi^0) | x_i\} = 0\) and consequently \(E(Z_{ni}) = 0\).

Because \(\{(y_i, x_i)\}_{i=1}^n\) are independent and identically distributed, we can show that \(s_n^2 = \alpha_n^T\Theta_{\xi^0}\alpha_n\).

To show \(\sum_{i=1}^n Z_{ni}/s_n \to N(0, 1)\) in distribution, we first check the Lindeberg condition and then the conclusion shall follow by the Lindeberg-Feller Central Limit Theorem. Specifically, for any
\( \epsilon > 0 \), we show that as \( n \to \infty \),
\[
\frac{1}{s_n^2} \sum_{i=1}^{n} E \left\{ Z_{ni}^2 \cdot 1(\lvert Z_{ni} \rvert > \epsilon s_n) \right\} \to 0.
\]
Due to the boundedness of the eigenvalues of \( \Sigma_{\xi^0} \), \( \alpha_n^T \Theta_{\xi^0} \alpha_n \geq \lambda_{\min}(\Theta_{\xi^0}) = 1/\lambda_{\max}(\Sigma_{\xi^0}) \geq c^{-1}_{\max} \).

On the other hand, by the Cauchy-Schwarz inequality, it holds almost surely that
\[
\left( \alpha_n^T \Theta_{\xi^0} x_i \right)^2 \leq \lVert \alpha_n \rVert_2^2 \cdot \lVert \Theta_{\xi^0} x_i \rVert_2^2 \leq \left( \lVert \Theta_{\xi^0} \rVert \cdot \lVert x_i \rVert \right)^2 \leq c^{-2}_{\min} \cdot \mathcal{O}(pK^2).
\]

Inside the indicator, it holds almost surely that
\[
\frac{Z_{ni}^2}{s_n^2} = \frac{[\hat{\rho}(y_i, x_i^T \xi_0)]^2 \left( \alpha_n^T \Theta_{\xi^0} x_i \right)^2}{n \alpha_n^T \Theta_{\xi^0} \alpha_n} \leq [\hat{\rho}(y_i, x_i^T \xi_0)]^2 \cdot c^{-2}_{\min} c_{\max} \cdot \mathcal{O}(K^2 \frac{p}{n}) \leq K_1^2 c^{-2}_{\min} c_{\max} \cdot \mathcal{O}(K^2 \frac{p}{n})
\]
where the last inequality follows from the boundedness of \( \hat{\rho}(y_i, x_i^T \xi_0) \) in Assumption 3. Hence, we have \( Z_{ni}^2/s_n^2 \to 0 \) almost surely as \( p/n \to 0 \). When \( n \) is large enough, \( Z_{ni}^2/s_n^2 < \epsilon^2 \) and all the indicators become 0. Therefore, by the Dominated Convergence Theorem, the Lindeberg condition holds and the Lindeber-Feller Central Limit Theorem guarantees the asymptotic normality.

Web Appendix A.2  Proof of Theorem 1

The invertibility of \( \hat{\Sigma}_{\xi} \) is shown in the proof of Lemma 2. Now with the bias decomposition Eq. (6) in the main text,
\[
n^{1/2} \alpha_n^T (\hat{b} - \xi^0) - n^{1/2} \alpha_n^T \hat{\Theta} \Delta = -n^{1/2} \alpha_n^T \hat{\Theta} P_n \hat{\rho}_{\xi^0},
\]
we first show that \( \alpha_n^T \hat{\Theta} \alpha_n - \alpha_n^T \Theta_{\xi^0} \alpha_n = o_p(1) \) and that
\[
n^{1/2} \alpha_n^T \hat{\Theta} P_n \hat{\rho}_{\xi^0} / (\alpha_n^T \Theta_{\xi^0} \alpha_n)^{1/2} = n^{1/2} \alpha_n^T \Theta_{\xi^0} P_n \hat{\rho}_{\xi^0} / (\alpha_n^T \Theta_{\xi^0} \alpha_n)^{1/2} + o_p(1),
\]
Then by Slutsky’s Theorem, the asymptotic distribution of the target \( n^{1/2} \alpha_n^T \hat{\Theta} P_n \hat{\rho}_{\xi^0} / (\alpha_n^T \Theta_{\xi^0} \alpha_n)^{1/2} \) can be derived by using the asymptotic distribution of \( n^{1/2} \alpha_n^T \Theta_{\xi^0} P_n \hat{\rho}_{\xi^0} / (\alpha_n^T \Theta_{\xi^0} \alpha_n)^{1/2} \), which has been proved in Lemma 3. In the final step, as long as \( n^{1/2} \alpha_n^T \hat{\Theta} \Delta = o_p(1) \), the asymptotic distribution of \( n^{1/2} \alpha_n^T (\hat{b} - \xi^0) / (\alpha_n^T \Theta \alpha_n)^{1/2} \) follows immediately.
According to Lemma 2, it follows that

$$ |\alpha_n^T \Theta \alpha_n - \alpha_n^T \Theta \alpha_n| = |\alpha_n^T (\Theta - \Theta) \alpha_n| \leq \|\Theta - \Theta\| \cdot \|\alpha_n\|^2 = o_P(1). $$

By the Cauchy-Schwartz inequality,

$$ \frac{1}{n} \left| \alpha_n^T \Theta \alpha_n - \alpha_n^T \Theta \alpha_n \right| \leq \frac{1}{n} \|\Theta - \Theta\| \cdot \|\alpha_n\|^2 $$

then we have

$$ \frac{1}{n} \left| \alpha_n^T \Theta \alpha_n - \alpha_n^T \Theta \alpha_n \right| \leq \frac{1}{n} \|\Theta - \Theta\| \cdot \|\alpha_n\|^2. $$

By definition,

$$ \|P_n \hat{\rho}\|^2 = \sum_{j=1}^p \{n^{-1} \sum_{i=1}^n x_{ij} \hat{\rho}(y_i, x_i^T \xi)\}^2 $$

$$ = n^{-2} \sum_{j=1}^p \sum_{i=1}^n \sum_{k=1}^n x_{ij} x_{kj} \hat{\rho}(y_i, x_i^T \xi) \hat{\rho}(y_k, x_k^T \xi). $$

With independent observations and $E\{x_{ij} \hat{\rho}(y_i, x_i^T \xi)\} = 0$ for any $i$, it follows that

$$ E\|P_n \hat{\rho}\|^2 = \frac{1}{n^2} \sum_{j=1}^p \sum_{i=1}^n E\{x_{ij}^2 \hat{\rho}^2(y_i, x_i^T \xi)\}. $$

By Assumptions 1 and 3, we have $|x_{ij} \hat{\rho}(y_i, x_i^T \xi)| \leq KK_1$ almost surely holds for all $i$ and $j$, so

$$ E\|P_n \hat{\rho}\|^2 = O(p/n). $$

This implies that $\|P_n \hat{\rho}\|^2 = O_P\{(p/n)^{1/2}\}$. Then we have

$$ \frac{1}{n} \left| \alpha_n^T \Theta \alpha_n - \alpha_n^T \Theta \alpha_n \right| \leq \frac{1}{n} \|\Theta - \Theta\| \cdot \|\alpha_n\|^2 = o_P\{(p/n)^{1/2}\} $$

which is $o_P(1)$ by our assumption in Theorem 1.

Finally, we prove $|n^{1/2} \alpha_n^T \hat{\Theta} \Delta| = o_P(1)$. By the Cauchy-Schwartz inequality, $|n^{1/2} \alpha_n^T \hat{\Theta} \Delta| \leq n^{1/2} \|\Theta \Delta\|^2$, we only need that $n^{1/2} \|\hat{\Theta} \Delta\|^2 = o_P(1)$. Note that

$$ \Delta = \frac{1}{n} \sum_{i=1}^n \left\{ \hat{\rho}(y_i, x_i^T \xi) - \hat{\rho}(y_i, x_i^T \xi) \right\} x_{ij} x_i^T (\xi^0 - \xi), $$
where \( a_i^* \) lies between \( x_i^T \xi \) and \( x_i^T \xi^0 \), i.e. \( |a_i^* - x_i^T \xi| \leq |x_i^T (\xi - \xi^0)| \). Then uniformly for all \( j \),

\[
|\Delta_j| \leq \frac{1}{n} \sum_{i=1}^{n} |\bar{\rho}(y_i, a_i^*) - \bar{\rho}(y_i, x_i^T \hat{\xi})| \cdot |x_i^T (\xi^0 - \hat{\xi})| \\
\leq \frac{1}{n} \sum_{i=1}^{n} c \cdot \text{Lip} |a_i^* - x_i^T \hat{\xi}| \cdot |x_i^T (\xi^0 - \hat{\xi})| \\
\leq c \cdot \text{Lip} \cdot \frac{1}{n} \sum_{i=1}^{n} |x_i^T (\xi^0 - \hat{\xi})|^2 \\
= c \cdot \text{Lip} \cdot O_P(s_0 \lambda^2) \\
= O_P(s_0 \lambda^2),
\]

where the last equality holds by Lemma 1. Since \( \|\Theta \xi^0\| = O(1) \) and \( \|\hat{\Theta} - \Theta \xi^0\| = o_P(1) \), it follows that \( \|\hat{\Theta}\| = O_P(1) \), and

\[
n^{1/2} \|\hat{\Theta} \Delta\|_2 \leq n^{1/2} \|\hat{\Theta}\| \cdot \|\Delta\|_2 \\
\leq n^{1/2} O_P(1) \cdot p^{1/2} \|\Delta\|_\infty \\
\leq O_P((np)^{1/2} s_0 \lambda^2).
\]

By the assumption of \((np)^{1/2} s_0 \lambda^2 = o(1)\) in Theorem 1, \( n^{1/2} \|\hat{\Theta} \Delta\|_2 = o_P(1) \). Applying Slutsky's Theorem and Lemma 3 gives the result.

Part (ii) in Theorem 1 can be proved using Cramér-Wold device. For any \( \tilde{a} \in \mathbb{R}^m \), let \( \alpha_n = A_n^T \tilde{a} \) in Theorem 1(i), which would still hold when \( \|\alpha_n\|_2 \leq c' \) for some constant \( c' > 0 \). In this case, \( \|\alpha_n\|_2 = \|A_n^T \tilde{a}\|_2 \leq \|A_n^T\| \|\tilde{a}\|_2 \leq c \|\tilde{a}\|_2 \) is upper bounded by a constant since \( \tilde{a} \) has a fixed dimension. Then, as \( n \to \infty \),

\[
n^{1/2} \tilde{a}^T A_n (\hat{b} - \xi^0) \overset{D}{\rightarrow} N(0, 1).
\]

The variance \( \|\tilde{a}^T A_n \hat{\Theta} A_n^T \tilde{a} - \tilde{a}^T A_n \Theta \xi^0 A_n^T \tilde{a}\| \leq \|\hat{\Theta} - \Theta \xi^0\| \|A_n^T \tilde{a}\|_2^2 = o_P(1) \). Hence, by Slutsky’s Theorem,

\[
n^{1/2} \tilde{a}^T A_n (\hat{b} - \xi^0) \overset{D}{\rightarrow} N(0, \tilde{a}^T F \tilde{a}).
\]
Web Appendix B. Additional Simulations

Web Appendix B.1 Simulation studies: large \( n \), diverging \( p \)

We examined the scenario with smaller sample sizes, where we simulated \( n = 500 \) observations with \( p = 20, 100, 200, 300 \) covariates in logistic regression models. The rest of the settings were identical to those with \( n = 1000 \) in the main text. Figures S1 – S3 display the results from three types of covariance structures, including the identity matrix, the autoregressive structure of order 1 or AR(1) with correlation 0.7, and the compound symmetry structure with correlation 0.7, respectively. Figure S3 shows that with \( n = 500, p = 300 \) and the compound symmetry structure, neither of the de-biased lasso methods worked well, which is not surprising given the relatively small sample size and highly correlated covariates.

We also varied the correlation \( \rho = 0.2 \) in the covariance matrix \( \Sigma_x \) for the autoregressive and compound symmetry structures to reflect the presence of less correlated covariates; see Figure S4 and Figure S5, respectively. These results are close to the independent covariate case. To summarize, our proposed refined de-biased lasso approach, in most cases, can provide the best bias correction and honest confidence intervals.

In Section 4, additional simulation results have been shown to demonstrate that generally \( \mu_n = 0 \) leads to the best performance empirically in Eq. (5). In the presented logistic regression setting, we simulate \( n = 500 \) observations and \( p = 40, 100, 200, 300, 400 \) covariates for 200 times. Covariates follow a multivariate Gaussian distribution with mean zero and AR(1) covariance matrix (\( \rho = 0.7 \)). Only two coefficients are non-zero (1 and 0.5) and the rest are noises. We pre-specify a sequence of values in \([0, 1]\) for the tuning parameter \( \mu_n \) in Eq. (5), equally spaced in log scale. The de-biased lasso estimator based on Eq. (5) is referred to by “tuning”.

Figure S6 (already shown in Section 4 of the main article) and Figure S7 show the simulation results for the coefficients \( \xi^0_j = 1 \) and \( \xi^0_j = 0.5 \) respectively, where the three columns correspond to average estimation bias, coverage probability for its 95% confidence interval, and the ratio between
its average model-based standard error and empirical standard error, over 200 replications. Since our main focus is good bias correction and honest confidence interval coverage, we find that over a very wide range of number of covariates, $\mu_n = 0$ performs the best empirically.

Web Appendix B.2 Simulation studies: large $p$, small $n$

We also present simulation studies that feature logistic regression models in the “large $p$, small $n$” setting, with $n = 300$ observations and $p = 500$ covariates. For simplicity, covariates are simulated from $N_p(0, \Sigma_x)$, where $\Sigma_{x,ij} = 0.7^{|i-j|}$, and truncated at $\pm 6$. In the true coefficient vector $\beta^0$, the intercept $\beta^0_0 = 0$ and $\beta^0_1$ varies from 0 to 1.5 with 40 equally spaced increments. To examine the impacts of different true model sizes, we arbitrarily choose $\bar{s}_0 = 2, 4$ or 10 additional coefficients from the rest in $\beta^0$, and fix them at 1 throughout the simulation. At each value of $\beta^0_1$, a total of 500 simulated datasets are generated. We focus on the de-biased estimates and inference for $\beta^0_1$ using the method of van de Geer et al. (2014).

Figure S8, with the true model size increasing from the top to the bottom, shows that the de-biased lasso estimate for $\beta^0_1$ has a bias which almost linearly increases with the true size of $\beta^0_1$. This undermines the credibility of the consequent confidence intervals. Meanwhile, the model-based variance overestimates the true variance for smaller signals and underestimates it for larger signals in the two models with smaller model sizes, as shown by the top two rows in Figure S8. This partially explains the over- and under-coverage for smaller and larger signals, respectively. Due to penalized estimation in node-wise lasso, the variance of the original de-biased lasso estimator is even smaller than the oracle maximum likelihood estimator obtained as if the true model were known; see the bottom two rows in Fig. S8. The empirical coverage probability decreases to about 50% as the signal $\beta^0_1$ goes to 1.5, and when the true model size reaches 5; see the middle row in Figure S8. The bias correction is sensitive to the true model size, which becomes worse for larger true models. We have also conducted simulations by changing the covariance structure of
covariates to be independent or compound symmetry with correlation coefficient 0.7 and variance 1, and have obtained similar results.

Web Appendix C. Demographics of the Boston Lung Cancer Survivor Cohort

Table S1 summarizes the demographics of the 1,374 individuals studied in the main text, stratified by their smoking status.

Web Appendix D. Discussion on the difference between sparsity assumptions in our work and van de Geer et al. (2014)

We first notice there are two kinds of sparsity parameters: one for the sparsity of regression coefficients (denoted by $s_0$), and the other for the sparsity of the inverse of the information matrix, $\Theta^{\xi}_0$ (denoted by $s_j$, the number of non-zero elements in the $j$th row of $\Theta^{\xi}_0$). The following clarifies the extent to which the assumptions of our Theorem 1 differs from those of van de Geer et al. (2014). For the model sparsity $s_0$, our assumption $s_0 \log(p)(p/n)^{1/2} \to 0$ is indeed more stringent than $s_0 \log(p)/\sqrt{n} \to 0$ required by van de Geer et al. (2014), whereas for the sparsity of the inverse information matrix, van de Geer et al. (2014) assumed $s_j = o(\sqrt{n/\log(p)})$ for all $j$ and we do not make any assumptions on $s_j$ directly. A related condition set by us is $p^2/n \to 0$, which is weaker than $s_j = o(\sqrt{n/\log(p)})$ by a logarithmic factor if $s_j \asymp p$.

Below we elaborate on how these sparsity differences lead to different results obtained by our manuscript and van de Geer et al. (2014), which indeed have different inferential objectives, and the rationale why our assumptions fit our inferential objectives.

First, these two works differ in inferential objectives. We aim to infer any linear combinations of the regression parameter, i.e. $\alpha_n^T \xi^0$, where the only constraint on $\alpha_n$ is $\|\alpha_n\|_2 = 1$ (in fact, bounded $\|\alpha_n\|_2$ would suffice). Thus, we have to control the behavior of the $(p+1) \times (p+1)$ matrix $\{\hat{\Theta} - \Theta^{\xi}_0\}$. In contrast, van de Geer et al. (2014) inferred individual components in $\xi^0$ one
at a time, making it sufficient to control the rates of \( \{ \hat{\Theta}_j - \Theta_{\xi^0,j} \} \) (here the subscript \( j \) indicates the \( j \)th row of a matrix) for one row at a time, and the node-wise lasso provides such required rates.

Second, besides the essential assumptions that both papers require (our Assumptions 1–4), van de Geer et al. (2014) has another important assumption that we do not need to assume, that is, \( \| X_{\beta^0,-j} \beta^0_{-j} \|_\infty = \mathcal{O}(1) \) (see their Theorem 3.3 (iv)), which results in \( \| X_{\hat{\Theta}j}^T \|_\infty = \mathcal{O}_P(K) \) in their condition (C5). In our notation, this assumption would be equivalent to the boundedness on \( \| \Theta_{\xi^0} x_i \|_\infty \) and would result in \( \| \hat{\Theta} x_i \|_\infty \) being bounded in probability. However, we have elected not to directly make such assumptions on the inverse of the informative matrix and its estimate as they may be closely related to the sparsity requirement of \( \Theta_{\xi^0} \) under Assumption 1, and may not hold or be verifiable in GLM settings.

Finally, we clarify that our specified order assumption on \( s_0 \) with respect to \( n \) and \( p \) is to ensure \( |n^{1/2} \alpha_n^T \hat{\Theta} \Delta| = o_P(1) \) in the proof of Theorem 1 (please see Pages 5–6 in Web Appendix A), which is for inference on any linear combinations of regression coefficients. However, if we had aimed for a weaker result of inferring an individual coefficient only as in van de Geer et al. (2014), we would have let \( \alpha_n = e_j \) (a \( p \)-dimensional vector with the \( j \)th element being 1 and all the other elements being zero) corresponding to drawing inference on the effect of the \( j \)th covariate, and also with a condition of \( \| \hat{\Theta} x_i \|_\infty = \mathcal{O}_P(1) \) as in van de Geer et al. (2014), we would have had

\[
|\sqrt{n} \hat{\Theta}_j \Delta| = |\sqrt{n} \frac{1}{n} \sum_{i=1}^{n} \left\{ \hat{\rho}(y_i, x_i^T \hat{\Theta}_j) - \hat{\rho}(y_i, x_i^T \hat{\Theta} x_i^T (\xi^0 - \hat{\xi})) \right\} \hat{\Theta}_j x_i^T (\xi^0 - \hat{\xi})| \\
\leq \sqrt{n} \frac{1}{n} \sum_{i=1}^{n} |\hat{\rho}(y_i, x_i^T \hat{\Theta}) - \hat{\rho}(y_i, x_i^T \hat{\Theta} x_i^T (\xi^0 - \hat{\xi}))| \cdot |\hat{\Theta}_j x_i| \cdot |x_i^T (\xi^0 - \hat{\xi})| \\
\leq \sqrt{n} \frac{1}{n} \sum_{i=1}^{n} c_{\text{Lip}} |x_i^T (\xi^0 - \hat{\xi})| \cdot \mathcal{O}_P(1) \cdot |x_i^T (\xi^0 - \hat{\xi})| \\
= \sqrt{n} \mathcal{O}_P(1) \frac{1}{n} \sum_{i=1}^{n} |x_i^T (\xi^0 - \hat{\xi})|^2 \\
= \mathcal{O}_P(\sqrt{n} s_0 \lambda^2).
\]

Therefore, to infer \( \xi^0_j \) alone, we would have reached the same assumption that \( s_0 \log(p) / \sqrt{n} \to 0 \) as in van de Geer et al. (2014) with \( \lambda \approx \sqrt{\log(p)} / n \).
In summary, our work may be meritorious by providing readers with these explicit rates for guaranteeing proper inferences when directly inverting the information matrix.

Figure S1. Simulation results: Bias, coverage probability, empirical standard error, and model-based standard error for $\beta_1^0$ in a logistic regression. Covariates are simulated from $N_p(0, I)$ before being truncated at $\pm 6$. The sample size is $n = 500$ and the number of covariates $p = 20, 100, 200, 300$. The oracle estimator, that is the maximum likelihood estimator under the true model, is plotted as a reference in orange solid lines. The methods in comparisons include our proposed refined de-biased lasso in olive dot-dash lines, the original de-biased lasso by van de Geer et al. (2014) in blue dashed lines, and the maximum likelihood estimation in red dotted lines.
Figure S2. Simulation results: Bias, coverage probability, empirical standard error, and model-based standard error for $\beta_0^i$ in a logistic regression. Covariates are simulated from $N_p(0, \Sigma_x)$ before being truncated at $\pm 6$, where $\Sigma_x$ has an autoregressive covariance structure of order 1 with $\rho = 0.7$. The sample size is $n = 500$ and the number of covariates $p = 20, 100, 200, 300$. The oracle estimator, that is the maximum likelihood estimator under the true model, is plotted as a reference in orange solid lines. The methods in comparisons include our proposed refined de-biased lasso in olive dot-dash lines, the original de-biased lasso by van de Geer et al. (2014) in blue dashed lines, and the maximum likelihood estimation in red dotted lines.
Figure S3. Simulation results: Bias, coverage probability, empirical standard error, and model-based standard error for $\beta_0$ in a logistic regression. Covariates are simulated from $N_p(0_p, \Sigma_x)$ before being truncated at $\pm 6$, where $\Sigma_x$ has a compound symmetry structure with $\rho = 0.7$. The sample size is $n = 500$ and the number of covariates $p = 20, 100, 200, 300$. The oracle estimator, that is the maximum likelihood estimator under the true model, is plotted as a reference in orange solid lines. The methods in comparisons include our proposed refined de-biased lasso in olive dot-dash lines, the original de-biased lasso by van de Geer et al. (2014) in blue dashed lines, and the maximum likelihood estimation in red dotted lines.
Figure S4. Simulation results: Bias, coverage probability, empirical standard error, and model-based standard error for $\beta_0$ in a logistic regression. Covariates are simulated from $N_p(0, \Sigma_x)$ before being truncated at $\pm 6$, where $\Sigma_x$ has an autoregressive covariance structure of order 1 with $\rho = 0.2$. The sample size is $n = 500$ and the number of covariates $p = 20, 100, 200, 300$. The oracle estimator, that is the maximum likelihood estimator under the true model, is plotted as a reference in orange solid lines. The methods in comparisons include our proposed refined de-biased lasso in olive dot-dash lines, the original de-biased lasso by van de Geer et al. (2014) in blue dashed lines, and the maximum likelihood estimation in red dotted lines.
**Figure S5.** Simulation results: Bias, coverage probability, empirical standard error, and model-based standard error for $\beta^0_1$ in a logistic regression. Covariates are simulated from $N_p(0_p, \Sigma_x)$ before being truncated at $\pm 6$, where $\Sigma_x$ has a compound symmetry structure with $\rho = 0.2$. The sample size is $n = 500$ and the number of covariates $p = 20, 100, 200, 300$. The oracle estimator, that is the maximum likelihood estimator under the true model, is plotted as a reference in orange solid lines. The methods in comparisons include our proposed refined de-biased lasso in olive dot-dash lines, the original de-biased lasso by van de Geer et al. (2014) in blue dashed lines, and the maximum likelihood estimation in red dotted lines.
Figure S6. Simulation results that verify the selection of the tuning parameter $\mu_{\text{in}} = 0$ in Eq. (5) for $\xi_j = 1$. 
Figure S7. Simulation results that verify the selection of the tuning parameter $\mu_n = 0$ in Eq. (5) for $\xi_j = 0.5$. 
Figure S8. Simulation results of a logistic regression with sample size $n = 300$ and $p = 500$ covariates. Covariates are simulated from $N_p(0_p, \Sigma_x)$ before being truncated at $\pm 6$, where $\Sigma_x$ has an autoregressive covariance structure of order 1 with $\rho = 0.7$. The left column presents estimation bias, the middle column presents empirical coverage probability, and the right column presents standard error, both model-based and empirical, of the estimated $\beta_0$. Horizontal panels correspond to models with 2, 4 and 10 additional signals fixed at 1 from the top to the bottom, respectively. In the left and middle columns, blue dashed lines represent the original de-biased lasso approach by van de Geer et al. (2014), and orange solid lines represent the oracle estimator. In the right column, blue dashed lines and black dotted lines represent the empirical standard error and the model-based standard error from the method of van de Geer et al. (2014), respectively, and orange solid lines for the empirical standard error of the oracle estimator.
